PREFACE.

AN author of a new trigonometry, at the present time, owes an explanation if not apology, both to teachers and students, for adding another to the already too numerous works upon this subject. The author was frequently applied to for opinions upon works extant and those proposed for publication, but found none that quite suited him; so the present work was undertaken to provide for his own classes and avoid further annoyance in being called upon to criticise others, even though it furnishes one more book for other critics to pass upon. The author found, however, when he had reduced his ideas to a form ready for print, that he did not differ from certain other writers as much as he, at first, expected to; still the many distinctive characteristics which remain will, we trust, commend themselves to others.

Attention is called to the fact that the trigonometrical functions are first defined and treated as ratios, but that afterwards they are represented by lines, which lines are so defined as to represent the functions. The latter may be made more prominent by any instructor

who desires so to do, although the chief object in the plan of the work was to furnish an aid to the memory for those who can remember geometrical representations more easily than abstract ratios.

We trust that the new notation in article 32 will meet with favor, as its adoption will remove an ambiguity which has thus far existed in this science. The functions as defined in article 16 are not restricted to quadrants, and their treatment afterwards in articles 23 to 30 are perfectly general, and hence it seems unnecessary after deducing equation (30) to make other and special demonstrations for particular limitations of the angles x and y. Similar remarks apply to equations following equation (30). Imaginary, or impossible functions have been introduced for the purpose of affording a greater variety in the exercises.

TRIGONOMETRY.

CHAPTER I.

FUNDAMENTAL PRINCIPLES.

1. *A geometrical quantity* is any form, figure, or magnitude conceived of in space.

A geometrical point is a figure from which magnitude is abstracted. It has no size and simply marks a place.

A geometrical line is that property of a figure which has length only; or from which breadth and thickness are abstracted.

A line may be generated by the movement of a point. If the generating point preserves a constant direction, the line generated is a *right line*, but if it changes its direction at every point, it generates a *curved line*. A right line is always understood unless otherwise stated. A right line is said to be given when its length and direction are known in reference to some other line assumed to be fixed.

2. **Angles.** *An angle* is the difference in direction of two lines. It is measured by means of some angle arbitrarily assumed for the unit. In reference to a figure representing an angle, it may be considered as the opening between two lines; the opening being greater as the inclination between the lines is greater.

Thus the direction or inclination of the line OF compared with that of OE is the angle between them. An angle is read by means of letters as EOF, the letter O at the vertex being the middle letter; but sometimes it is referred to by simply naming the letter at the vertex as O.

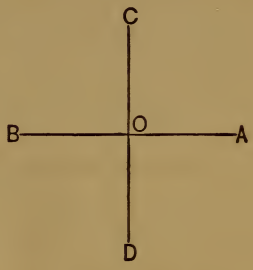
An angle may be denoted by a single letter, as x, y, etc., or by a Greek letter as α, β, γ . . . θ, φ, etc., in which case we have

$$x = EOF, \quad . \quad . \quad . \quad \text{or } \varphi = EOF, \quad . \quad . \quad . \quad \text{etc.}$$

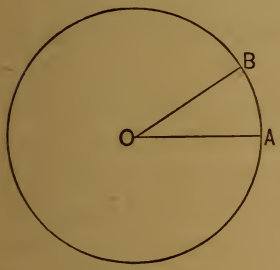
An angle may be generated by revolving a line about a point. Thus, the angle EOF may be conceived to be generated by revolving a line from OE into the final position of OF. The line OE from which OF starts in the rotation, is called the *initial line*, and OF in its final position, the *terminal line*. The moving line, OF, is called the *generatrix*. The point O is the *origin*, *vertex*, or *pole*. An angle in this case measures the amount of rotation of the generating line.

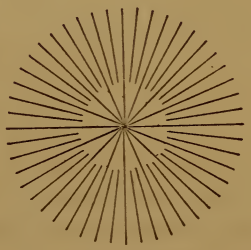
If two lines do not intersect, they are conceived to make the same angle as two other lines passing through a point and parallel respectively to the given lines. Thus, the angle between the lines AB and CD, whether in the same plane or not, is the same as between the lines OE and OF, drawn through the point O and parallel respectively to CD and AB.

3. **Measurement of Angles.** If two lines, AB and CD, so intersect as to make the four angles at O equal, the lines will be mutually perpendicular, and each of the angles is called a *right angle.* A right angle is sometimes taken as a unit angle. An acute angle is less than a right angle, and an obtuse angle greater.



An angle may be measured by the arc subtending it, the centre of the arc being at the vertex of the angle. For, the radius being constant, the angle and arc will be generated by the same amount of rotary motion of the generating line OB, and of the point B. In order to compare angles by means of arcs, the radius must be constant, and, unless otherwise stated, it will be considered as unity. Then will π be the length of a semi-circumference; and $\frac{1}{2}\pi$ of one-fourth of a circumference and hence will subtend a right angle, π will subtend two right angles, $\frac{3}{2}\pi$ three right angles and, generally, $\frac{1}{2}n\pi$, n right angles, n being any integer. We say, for brevity, $\frac{1}{2}\pi$ is a right angle, $\frac{1}{4}\pi$ is one-half of a right angle, etc. This method of measuring an angle is called *circular measure.*

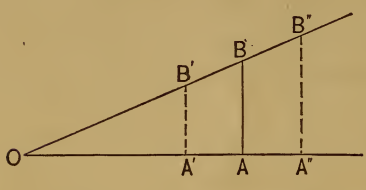




If 360 lines radiate from a point, making equal angles between the consecutive lines, each

angle is, by common consent, called *a degree*. This is the unit-angle commonly employed in practice.

Hence, we say, that the complete revolution of a line about a point generates 360°, and that in one right angle there are 90 degrees. Also an arc $\frac{1}{2}\pi$ subtends an angle of 90 degrees, $\frac{1}{4}\pi$ of 45 degrees, and so on. And for brevity we sometimes say, $\frac{1}{2}\pi$ equals 90 degrees, $\frac{1}{4}\pi$ equals 45 degrees, etc.



An angle may also be measured by means of certain other lines bounding it. Thus, if from any points B', B, B'', etc., in the line OB, perpendiculars, $B'A'$, BA, $B''A''$, etc., be let fall upon OA we have from similar triangles

$$\frac{A'B'}{OA'} = \frac{AB}{OA} = \frac{A''B''}{OA''} = a\ constant$$

for any fixed angle; hence, if this ratio be determined in any manner, it may be used as a measure of that angle. Thus, this ratio for an angle $AOB = 45$ degrees, will be unity; hence, conversely, when this ratio is 1 we know that the angle O is 45 degrees. The ratio for other angles may be found and the results tabulated. We also have

$$\frac{OA'}{OB'} = \frac{OA}{OB} = a\ constant$$

for a given angle. Similarly, ratios may be found between other lines about the angle. This mode of measuring angles forms the basis of the science which we are to consider.

$(\sin A)^n$, or $\sin^n A$; the latter being the more common notation; and similarly for other functions. The sine of the nth power of the angle is written $\sin A^n$; and similarly for the other functions. The sine of n times an angle is written $\sin (nA)$, or simply $\sin nA$; and similarly for the other functions. The reciprocal of the sine of A is written $(\sin A)^{-1}$ or $\frac{1}{\sin A}$, but not $\sin^{-1} A$, the latter notation being often employed for another purpose. The functions may be multiplied and divided in the usual manner; thus $\sin A \cos A$ implies that $\cos A$ is multiplied by $\sin A$, and similarly for the others.

6. One quantity is said to be a function of another when it is so related to the other that a change in the value of the latter causes a change in the value of the former, thus in the expressions

$$y = 3x^2 - ax, \qquad y = \log x, \qquad y = \sin x, \qquad y = \tan x,$$

y is said to be a function of x; and the first is called an algebraic function, the second is logarithmic, and the others trigonometrical. All functions not *algebraic* are called *transcendental.* When the form of a function is unknown, or when brevity alone is desired, it may be written

$$y = F(x), \qquad \text{or } y = f(x), \qquad \text{or } y = \varphi(x);$$

all of which are read "y is a function of x." In these expressions F, f, φ, are not quantities but symbols implying some *form* of an expression.

7. *Trigonometry* is that science which treats of the

properties and relations of trigonometrical functions, and of their use in the solution of triangles. It is considered in three parts, viz. :

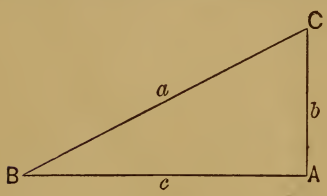
Analytical Trigonometry treats of the abstract properties of trigonometrical functions.

Plane Trigonometry treats of the solution of plane triangles by means of trigonometrical functions.

Spherical Trigonometry treats of the solution of spherical triangles by means of trigonometrical functions.

EXERCISES.

1. In the right triangle BAC, if $BA = 4$, $AC = 3$, what will be the sine of the acute angles ?



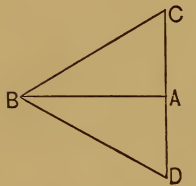
[We have $BC = \sqrt{4^2 + 3^2} = 5$; hence, according to the definition, $\sin B = \frac{3}{5}$ and $\sin C = \frac{4}{5}$.]

2. Find the value of the other seven trigonometrical functions of B in the preceding exercise.

3. Find the trigonometrical functions of 45°.

In this case $BA = AC$, and $BC = BA\sqrt{2}$. It will be found that $\sin 45° = \frac{1}{2}\sqrt{2} = \cos 45°$; $\tan 45° = 1 = \cot 45°$; $\sec 45° = \sqrt{2} = \csc 45°$.

4. Find the trigonometrical functions of 30°.



Let CBD be an equilateral triangle, then will each of the angles be 60°. From B drop the perpendicular BA, then will $BAC = 90°$, $CBA = 30°$, $AC = AD = \frac{1}{2}CD = \frac{1}{2}BC$;

$$\therefore \sin 30° = \frac{AC}{BC} = \frac{\frac{1}{2}BC}{BC} = \frac{1}{2} ; \cos 30° = \frac{BA}{BC} = \frac{\sqrt{BC^2 - AC^2}}{BC} = \frac{\sqrt{4AC^2 - AC^2}}{2AC} = \frac{1}{2}\sqrt{3} ;$$

$$\tan 30° = \sqrt{\tfrac{1}{3}} ; \quad \cot 30° = \sqrt{3}.$$

5. Find the trigonometrical functions of 60°.
If $B = 30°$ in the right triangle BAC, then will $C = 60°$.

$$\sin 60° = \frac{AB}{CB} = \tfrac{1}{2}\sqrt{3} = \cos 30° ; \qquad \cos 60° = \tfrac{1}{2} = \sin 30° ;$$

$$\tan 60° = \sqrt{3} = \cot 30° ; \qquad \cot 60° = \tfrac{1}{3}\sqrt{3} = \tan 30°.$$

6. Show that $\sin^2 A + \cos^2 A = 1$.
[We have from group (*A*)

$$\sin^2 A + \cos^2 A = \frac{p^2}{h^2} + \frac{b^2}{h^2} = \frac{p^2 + b^2}{h^2} = \frac{h^2}{h^2} = 1.]$$

7. Show that $\sec^2 A = 1 + \tan^2 A$.

8. Show that

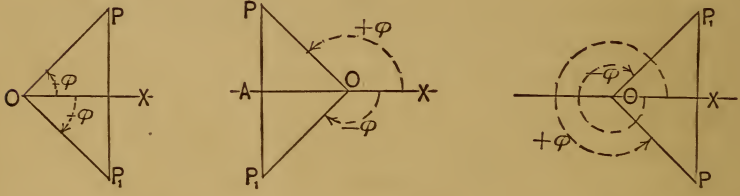
$$\tan A = \frac{\sin A}{\cos A} = \frac{\sin A}{\sqrt{1 - \sin^2 A}} = \frac{1}{\sqrt{\csc^2 A - 1}}.$$

Prove the following equations :

9. $\tan A \cot A = 1$.
10. $\cos A = \sin A \cot A$.
11. $(\sin A + \cos A)^2 + (\sin A - \cos A)^2 = 2$.
12. $\sin^2 A - \cos^2 B = \sin^2 B - \cos^2 A$.
13. $\tan A + \cot A = \sec A \csc A$.
14. $(\sin^2 \theta + \cos^2 \theta)^n = 1$.
15. $(\sin^2 \varphi - \cos^2 \varphi)^2 = 1 - 4\cos^2 \varphi + 4\cos^4 \varphi$. (Observe that from Example 6 we have $\sin^2 \varphi = 1 - \cos^2 \varphi$.)
16. $\dfrac{\tan \varphi + \tan \theta}{\cot \varphi + \cot \theta} = \tan \varphi . \tan \theta$.
17. $3 \sin 60° - 4 \sin^3 60° = 4 \cos^3 30° - 3 \cos 30°$.
18. $\sin^2 (\theta + \varphi) + \cos^2 (\theta + \varphi) = 1$.
19. $\sin 45° + \cos 30° = \tfrac{1}{2}(\sqrt{2} + \sqrt{3})$.
20. $\tan 30° . \cos 45° = \tfrac{1}{2}$.
21. $\dfrac{1 - \sin \varphi}{1 + \sin \varphi} = (\sec \varphi - \tan \varphi)^2$.
22. $\sin 60° . \cot 60° = \tfrac{1}{2}$.
23. $(\tan A + \cot A) \sin A . \cos A = 1$.
24. $\tan 30° . \tan 60° . \cos 45° . \sec 45° = 1$.
25. $\cos x . \tan x = \sin x$.
26. $\csc x . \tan x = \sec x$.

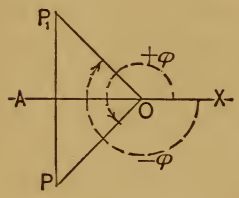
Analytical Trigonometry.

8. We now consider the principles according to which the functions may be so extended as to be more general. The algebraic signs + and − applied to a line indicate opposite directions. Thus, if a line generated by a point moving in one direction be *positive*, the opposite direction will be *negative;* the former of which will be indicated by + and the latter by −. If AB be positive BA and AC will be negative.



9. *Angles and arcs* may also be affected by the signs + and −. Thus, if the angle XOP, generated by a

left-handed rotation, be considered *positive*, the angle XOP_1, generated by a right-handed rotation, will be *negative*. The signs + and − indicate relative direction of motion in generating a magnitude.



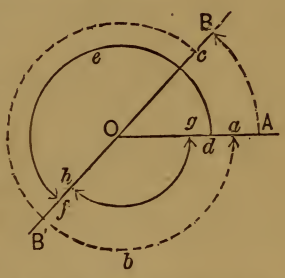
The angle POX would also be negative, the order of the letters indicating that the rotation is from P to X, or right handed. The positive arc is here indicated by $+\varphi$, and the negative arc by $-\varphi$.

Since the above relations are arbitrary, either may be assumed as positive, but when once chosen it must be

used in that sense through that discussion. According to custom, left-handed rotation will be understood unless otherwise stated.

10. *Theoretically, angles have no limits* as to size, for the generating line may be revolved about the pole any number of times; still all possible directions in a plane will have been passed over by one revolution of the radius.

If φ be an angle less than 360°, the terminal position of the generating line will be the same for the angles φ, $2\pi + \varphi$, $4\pi + \varphi$ . . . $2n\pi + \varphi$, where n is zero or an integer either positive or negative.



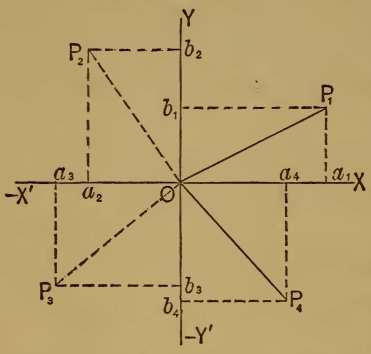
11. If OB be the terminal line, any point in it, as B, may be determined by any one of the four following ways: By revolving a line from OA in a positive direction through an angle AOB until it passes through the point B, when it will be determined by the angle AOB and distance OB. Or, by revolving the generating line *negatively* through the angle *abc* until it passes through B. Or, by revolving it *positively* through the angle *def* into the position OB', so that if prolonged negatively through O it will pass through B. Or, by revolving it negatively through the angle *gh* into the latter position.

To represent these algebraically, let ρ = the distance OB, and $\varphi = AOB$; then the point B may be found by either one of the four following combinations:—

$$\left.\begin{matrix} +\rho \\ +\varphi \end{matrix}\right\}; \quad \left.\begin{matrix} +\rho \\ -(360 - \varphi) \end{matrix}\right\}; \quad \left.\begin{matrix} -\rho \\ +(180 + \varphi) \end{matrix}\right\}; \quad \left.\begin{matrix} -\rho \\ -(180 - \varphi) \end{matrix}\right\}.$$

The negative radius, $-\rho$, is unnecessary in this science, and hence will not be further considered, but both positive and negative angles will be used.

12. **Coördinates.** Two mutually perpendicular lines XX', YY', when used as lines of reference, are called coördinates, and the lines are called *coördinate axes.* The horizontal line XX' is called the axis of *abscissas,* and the perpendicular line YY' is called the axis of *ordinates.* The angle XOY is the first quadrant; YOX', the second; $X'OY'$, the third; and $Y'OX$, the fourth quadrant.



Coördinate axes may be oblique, but as used in this work it should be observed that they must be mutually perpendicular.

13. *The abscissa* of a point is its distance from the axis of ordinates YY', measured on a line parallel to the axis of abscissas. The abscissas to the right of YY' will be considered *positive,* those to the left *negative.* Thus, the abscissa of P_1 will be $+ b_1P_1$; of P_2, $- b_2P_2$; of P_3, $- b_3P_3$; and of P_4, $+ b_4P_4$. The letters b_1, b_2, etc., are placed before P_1, P_2, etc., so that the order of the letters will indicate the direction of P_1, P_2, etc., from the axis YY'.

14. *The ordinate* to any point is its distance from the axis of abscissas measured on a line parallel to the axis of ordinates. The ordinates above XX' will be considered *positive,* those below, *negative.* Thus, the ordi-

nate of P_1 will be $+ a_1P_1$; of P_2, $+ a_2P_2$; of P_3, $- a_3P_3$; of P_4, $- a_4P_4$.

The abscissa and ordinate of a point are together called its *coördinates.*

15. *The signs of the coördinates* in the four quadrants will be

	1st Quadrant.	2d Quadrant.	3d Quadrant.	4th Quadrant.
Abscissa,	+	−	−	+
Ordinate,	+	+	−	−

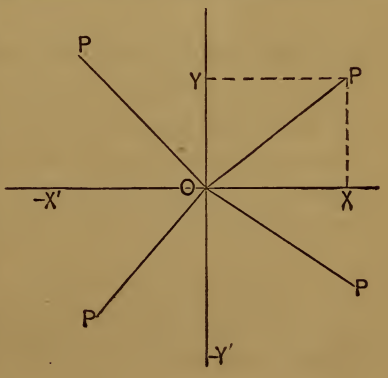
EXERCISES.

Show in what quadrant the revolving line will be when it has described the angles, n being an integer :

1. $120°$	2. $390°$	3. $490°$
4. $700°$	5. $-120°$	6. $-490°$
7. $\frac{2}{3}\pi$	8. $10\frac{1}{4}\pi$	9. $-8\frac{1}{4}\pi$.
10. $2n\pi$	11. $(2n+\frac{1}{2})\pi$	12. $-(4n-\frac{1}{4})\pi$.
13. $(6n+1)\frac{\pi}{3}$.	14. $(6n-2)\frac{\pi}{3}$	15. $-(8n+2)\frac{\pi}{4}$..

---

16. Letting XOP be any angle x, O the origin of coördinates, $OP = r$, the radius vector, or simply the radius, being the distance from the origin to any point P in the terminal side of the angle x, $XP = o$, the ordinate to the point P, $YP = a$, the abscissa to the same point, where r, o, a, are initial letters of the quantities



they respectively represent; we define the trigonometrical functions in a more general way, as follows:

$$\left.\begin{aligned}
\sin x &= \frac{ordinate}{radius} &&= \frac{XP}{OP} = \frac{o}{r} \\
\cos x &= \frac{abscissa}{radius} &&= \frac{YP}{OP} = \frac{a}{r} \\
\tan x &= \frac{ordinate}{abscissa} &&= \frac{XP}{OX} = \frac{o}{a} \\
\cot x &= \frac{abscissa}{ordinate} &&= \frac{OX}{XP} = \frac{a}{o} \\
\sec x &= \frac{radius}{abscissa} &&= \frac{OP}{OX} = \frac{r}{a} \\
\csc x &= \frac{radius}{ordinate} &&= \frac{OP}{XP} = \frac{r}{o} \\
\text{vsn } x &= \frac{r - abscissa}{radius} &&= \frac{r-a}{r} \\
\text{cvs } x &= \frac{r - ordinate}{radius} &&= \frac{r-o}{r}
\end{aligned}\right\} (B).$$

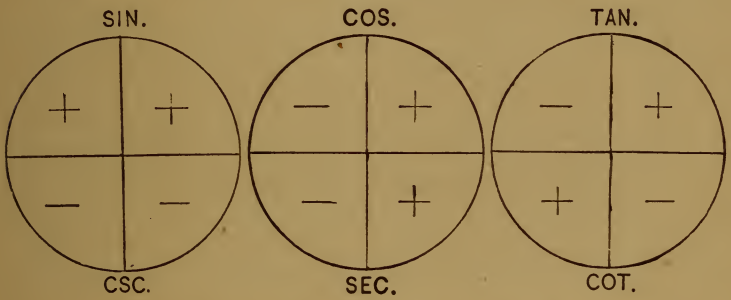
in which o and a may be plus or minus.

The definitions on page 6, were, strictly speaking, for an acute angle, but by giving + and − signs to o and a as may be necessary, the definitions in group (B) are general, and applicable to any angle from OX to the terminal position of the generating line.

17. *Signs of the functions.* The signs of the co-ordinates given in article 15, applied to group (B), gives for the signs of the functions for the several quadrants:

Functions.	1st quad.	2d quad.	3d quad.	4th quad.
sin and csc	+	+	−	−
cos and sec	+	−	−	+
tan and cot	+	−	+	−
vsn and cvs	+	+	+	+

The sine and cosine have like signs in the 1st and 3d quadrants, and the tangent and cotangent are positive in the same quadrants.



18. *Limiting values of the ordinate and abscissa.* For zero degrees, the terminal and initial lines coincide, hence the ordinate will be zero, and the abscissa equal r. Symbolically, we have for $x = 0°$, $a = r$, and $o = 0$. In this way we find from the figure that for

$$\begin{aligned}
x &= 0°, & a &= r, & o &= 0,\\
x &= 90°, & a &= 0, & o &= r,\\
x &= 180°, & a &= -r, & o &= 0,\\
x &= 270°, & a &= 0, & o &= -r,\\
x &= 360°, & a &= r, & o &= 0;
\end{aligned}$$

the last being the same as the first, and after this the values repeat themselves at the end of every quadrant.

19. **Limiting values of the functions.** The values of a and o given in the preceding article, substituted in group (B) give

Functions.	Angles.			
	0°	90°	180°	270°
sin	∓ 0	1	± 0	-1
cos	1	± 0	-1	∓ 0
tan	∓ 0	$\pm \infty$	∓ 0	$\pm \infty$
cot	$\mp \infty$	± 0	$\mp \infty$	± 0
sec	1	$\pm \infty$	-1	$\mp \infty$
csc	$\mp \infty$	1	$\pm \infty$	-1
vsn	$+0$	1	2	1
cvs	1	0	1	2

[The order of the signs $\pm$ indicates that the function has passed from $-$ to $+$; that is just before the generating line reached the given angle the sign of the function was $-$, and was $+$ immediately after passing it.]

20. **Relative values of the functions.** From group (B) we derive the following:

$$\frac{\sin x}{\cos x} = \frac{\frac{o}{r}}{\frac{a}{r}} = \frac{o}{a} = \tan x, \qquad (1)$$

$$\frac{\cos x}{\sin x} = \frac{a}{o} = \cot x; \qquad (2)$$

that is, *The tangent of any angle equals the ratio of the sine of that angle to its cosine;* and

The cotangent of an angle equals the ratio of the cosine to the sine.

Also from the same group we find the following combinations of the functions equal to unity:

$$\sin^2 x + \cos^2 x = \frac{a^2 + o^2}{r^2} = \frac{r^2}{r^2} = 1, \tag{3}$$

$$\tan x \cot x = 1, \tag{4}$$

$$\sin x \csc x = 1, \tag{5}$$

$$\cos x \sec x = 1, \tag{6}$$

$$\cos x + \text{vsn } x = 1, \tag{7}$$

$$\sin x + \text{cvs } x = 1. \tag{8}$$

21. *Each function may be expressed in terms of any one of the other seven.* Thus, from equations (3), (5), (8), of the preceding article we have directly

$$\sin x = \sqrt{1 - \cos^2 x} = \frac{1}{\csc x} = 1 - \text{cvs } x,$$

which gives the value of $\sin x$ in terms of cos, csc, and cvs. To find it in terms of the tangent, we have from (1),

$$\sin x = \tan x \cos x$$

from (3),

$$= \tan x \sqrt{1 - \sin^2 x};$$

$$\therefore \sin^2 x = \tan^2 x - \tan^2 x \sin^2 x,$$

transposing,

$$(1 + \tan^2 x) \sin^2 x = \tan^2 x;$$

$$\therefore \sin x = \frac{\tan x}{\sqrt{1 + \tan^2 x}}; \tag{9}$$

which is the required result.

From (4) we have

$$\tan x = \frac{1}{\cot x}, \tag{10}$$

which substituted in the preceding equation gives

$$\sin x = \frac{1}{\sqrt{1 + \cot^2 x}};$$

and so on for the other two functions. In this way the following table may be formed.

Given Functions.	Required Functions.					
	$\sin$	$\cos$	$\tan$	$\cot$	$\sec$	$\csc$
$\sin$	$\sin$	$\sqrt{1 - \cos^2}$	$\frac{\tan}{\sqrt{1 + \tan^2}}$	$\frac{1}{\sqrt{1 + \cot^2}}$	$\frac{\sqrt{\sec^2 - 1}}{\sec}$	$\frac{1}{\csc}$
$\cos$	$\sqrt{1 - \sin^2}$	$\cos$	$\frac{1}{\sqrt{1 + \tan^2}}$	$\frac{\cot}{\sqrt{1 + \cot^2}}$	$\frac{1}{\sec}$	$\frac{\sqrt{\csc^2 - 1}}{\csc}$
$\tan$	$\frac{\sin}{\sqrt{1 - \sin^2}}$	$\frac{\sqrt{1 - \cos^2}}{\cos}$	$\tan$	$\frac{1}{\cot}$	$\sqrt{\sec^2 - 1}$	$\frac{1}{\sqrt{\csc^2 - 1}}$
$\cot$	$\frac{\sqrt{1 - \sin^2}}{\sin}$	$\frac{\cos}{\sqrt{1 - \cos^2}}$	$\frac{1}{\tan}$	$\cot$	$\frac{1}{\sqrt{\sec^2 - 1}}$	$\sqrt{\csc^2 - 1}$
$\sec$	$\frac{1}{\sqrt{1 - \sin^2}}$	$\frac{1}{\cos}$	$\sqrt{1 + \tan^2}$	$\frac{\sqrt{1 + \cot^2}}{\cot}$	$\sec$	$\frac{\csc}{\sqrt{\csc^2 - 1}}$
$\csc$	$\frac{1}{\sin}$	$\frac{1}{\sqrt{1 - \cos^2}}$	$\frac{\sqrt{1 + \tan^2}}{\tan}$	$\sqrt{1 + \cot^2}$	$\frac{\sec}{\sqrt{\sec^2 - 1}}$	$\csc$

EXERCISES.

1. In what quadrants may A be if $\sin A = -0.567$?
2. If $\sin x = -\frac{1}{2}$, find the other functions when the terminal line is in the third quadrant.
3. Find the functions when $\tan x = 2$, and the terminal line is in the third quadrant.
4. Find x when $\sin x = \cos x$.

   [Make $\cos x = \sqrt{1 - \sin^2 x}$, solve and compare the result with exercise 3, page 8.]

5. Find x when $\sin x = \tan x$. *Ans.* $x = 0$.
6. Find the trigonometrical functions corresponding to $\cot x = 2$.
7. If $\tan x = 2 \cos x$, find $\sin x$ in terms of $\cot x$.

   [$\tan x = \dfrac{1}{\cot x}$, and $\cos x = \sqrt{1 - \sin^2 x}$; hence we find

   $$\sin x = \sqrt{1 - \frac{1}{4 \cot^2 x}}$$]

8. If $\cot x = 2 \tan x$, find $\sin x$ in terms of $\cos x$.
9. Find $\sin x$ from the equation $2 \sin^2 x - 3 \sin x = 1$.

   [Here $\sin x$ is the unknown quantity, and the equation is to be solved as a complete quadratic.]

10. Find $\tan x$ from the equation $a \tan x + b \cot x = c$.

    [Substitute $\cot x$ from equation (4) and solve.]

11. Find $\sin x$ from the equation $3 \sin x - 2 \cos x = 2 \operatorname{vsn} x$.

    Ans. $\frac{2}{3}$.

12. Show that $\sin^2 \frac{1}{2}x + \cos^2 \frac{1}{2}x = 1$.
13. Show that $\sin^2 nx = 1 - \cos^2 nx$.
14. What does $\sin^2 (1 - \frac{1}{2}x) + \cos^2 (1 - \frac{1}{2}x)$ equal ?
15. In a right triangle, if the base be $3a$ and the perpendicular $4a$, find each of the eight trigonometrical functions.
16. Given $2 \sin x = 3 \cos y$, and $\tan y = 3 \cos x$, to find $\sin x$.

    [We have from equation (1) $\tan y = \dfrac{\sin y}{\cos y}$, which, by means of equation (3), becomes $\dfrac{\sqrt{1 - \cos^2 y}}{\cos y}$, and this in the second of the given equations gives

    $$1 - \cos^2 y = 9 \cos^2 x \cos^2 y,$$

from which finding $\cos y$ and substituting in the first of the given equations, gives $\sin x = \pm 0.89 +$ or $\pm 0.56 +$.]

17. Given $\sin x + \cos y = 1$, and $\sin x \cos y = -\frac{1}{2}$, find $\sin x$ and $\sin y$.
18. Solve the simultaneous equations $\tan x \cot y = 2$, and $\sin x \cos y = \frac{1}{4}$.
19. Find $\sin x$ from the equations $a^{\sin x} = b^{\cos y}$, and $\sin^a x = \cos^b y$.

[From the first equation, $\sin x \log a = \cos y \log b$; from the second, $\cos y = (\sin x)^{\frac{a}{b}}$ Substituting gives

$$\sin x = \frac{\log b}{\log a}(\sin x)^{\frac{a}{b}}, \quad \text{or } \sin x \left[1 - \frac{\log b}{\log a}(\sin x)^{\frac{a}{b}-1}\right] = 0;$$

$$\therefore \sin x = 0, \text{ or } \sin x = \left(\frac{\log a}{\log b}\right)^{\frac{b}{a-b}}.]$$

20. Find y from the equations $(\tan x)^{\cot y} = 5$, $(\tan x)^{\cos y} = \frac{1}{2}$.
21. Find the values of x from the equation

$$\sin x \cos \tfrac{1}{2}x \tan \tfrac{1}{4}x = 0.$$

[Each factor may be zero, hence $\sin x = 0$, and $x = 0, \pi, 2\pi$, &c.
If $\cos \frac{1}{2}x = 0$, then $\frac{1}{2}x = \frac{1}{2}\pi, \frac{3}{2}\pi$, &c., and $x = \pi, 3\pi, 5\pi$, &c.
If $\tan \frac{1}{4}x = 0$, then $\frac{1}{4}x = 0, \pi, 2\pi$, &c., and $x = 0, 4\pi, 8\pi$, &c.]

---

22. **Functions of negative angles.** If the angle be negative, and numerically less than 90°, it will be below the line OX in the figure on page 21, and the ordinate o will be negative, or $-o$, while the abscissa will be positive, or $+a$; and we have

$$\sin(-x) = \frac{-o}{r} = -\frac{o}{r} = -\sin x. \tag{11}$$

Similarly,

$$\cos(-x) = \frac{a}{r} = \cos x. \tag{12}$$

It may be shown that the same relation exists when the angle exceeds 90°; hence we have generally,

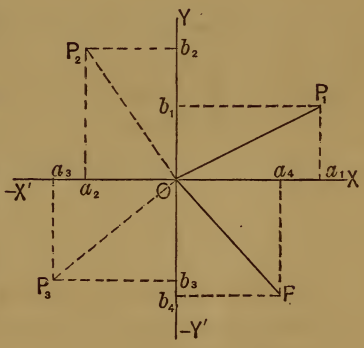
$$\cos(-x) = \cos x, \qquad \sec(-x) = \sec x, \tag{13}$$

$$\left.\begin{aligned} \sin(-x) &= -\sin x, & \tan(-x) &= -\tan x, \\ \csc(-x) &= -\csc x, & \cot(-x) &= -\cot x. \end{aligned}\right\} \tag{14}$$

That is, *The cosine and secant of a negative angle are identical with that of a positive angle of the same magnitude; but the sine, cosecant, tangent, and cotangent of a negative angle are* MINUS *the like-named function of an equal positive angle.*

23. *The complement* of an angle is "90° *minus* the angle." Thus the complement of the angle XOP_1 will be $90 - XOP_1 = P_1OY$; of XOP_2, $90° - XOP_2 = -YOP_2$; and so on.

The complement of an angle exceeding 90° will be negative, and the complement of a negative angle will be positive, and exceed 90°.

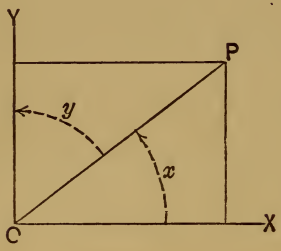


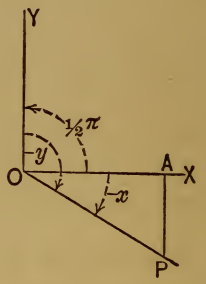
24. *The supplement* of an angle is "180° *minus* the angle." Thus the supplement of XOP_2 will be $180° - XOP_2 = P_2OX'$.

25. *Complementary functions.* Let $XOP = x$, and $POY = y$; then, because of alternate angles (Fig. on p. 22),

$$x = XOP = OPY = 90° - y.$$

The angle x may be produced in this case, by revolving the generating line positively 90°, or to OY, then negatively through an angle $y = YOP$, giving $x = XOP$.



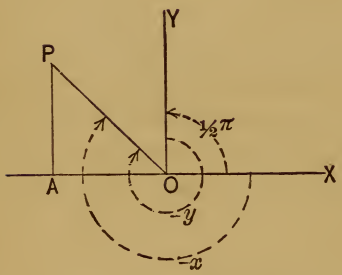


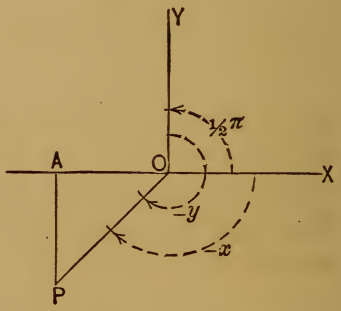
From the figure and group (B) we have

$$\frac{o}{r} = \sin XOP = \sin x = \sin (90° - y),$$

and $$\frac{o}{r} = \cos POY = \cos y;$$

$$\therefore \sin XOP = \cos POY;$$





and this is true for any value of y; and corresponding results may be found for the other functions; hence we have for *the functions of* $90° - y$,

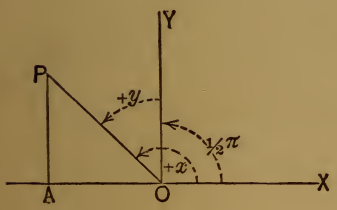
$$\left.\begin{array}{ll} \sin(90^\circ - y) = \cos y. & \cos(90^\circ - y) = \sin y. \\ \tan(90^\circ - y) = \cot y. & \cot(90^\circ - y) = \tan y. \\ \sec(90^\circ - y) = \csc y. & \csc(90^\circ - y) = \sec y. \end{array}\right\} (16)$$

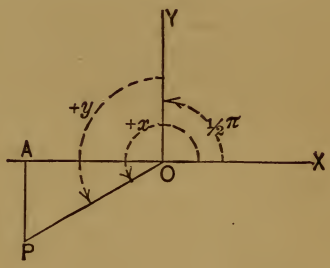
That is, *The sine, tangent, or secant of an angle equals the co-function of its complement.*

[Cosine may be considered as an abbreviation for "the sine of the complement of an angle," and similarly for cotangent and cosecant.]

26. *Functions of* $90^\circ + y$.

Writing $-y$ for y in the first of equations (16), the left member will become $\sin x = \sin[90^\circ - (-y)] =$





$\sin[90^\circ + y]$, and the right member, $\cos(-y)$, which being reduced by the first of equations (14) becomes $\cos y$; and this is true whatever be the magnitude of y. Treating the other functions in the same manner, or by means of the figure, we have

$$\left.\begin{array}{ll} \sin(90^\circ + y) = \cos y. & \cos(90^\circ + y) = -\sin y. \\ \tan(90^\circ + y) = -\cot y. & \cot(90^\circ + y) = -\tan y. \\ \sec(90^\circ + y) = -\csc y. & \csc(90^\circ + y) = \sec y. \end{array}\right\} (17)$$

EXERCISES.

1. What is the complement of 18°, 100°, 190°, − 40° ?
2. What is the supplement of 15°, 120°, 200°, 300°, − 50° ?
3. Construct the angle $90° + y$, when $y > 180°$ and $< 270°$.
4. Construct the angle $90° + y$, when $y > 270°$ and $< 360°$.
5. If $\sin x = \cos nx$, find x.

   [From (16) $\sin x = \cos (90° - x)$, which substituted in the example gives $\cos (90° - x) = \cos nx$; $\therefore\ 90° - x = nx$, and $x = \frac{90°}{1 + n}$.]
6. If $\cos x = \sin 2x$, find x.
7. If $\tan x = \cot nx$, find x.
8. Find x from the equation $\cot (90° - x) = \tan (45° - x)$.
9. Given $2x + y = \frac{1}{2}\pi$ and $\sin x = \cos 2y$, find x and y.
10. Given $\sin x = \cos 3y$ and $\tan 3x = \cot y$, to find x and y.
11. Given $\sin 3x = \cos 2y$ and $3x + 2y = 90°$, to find x and y.
12. Prove that $(a \cos \beta)^2 + (a \sin \beta \sin \gamma)^2 + (a \sin \beta \cos \gamma)^2 = a^2$.
13. What angle is that of which the cotangent equals twice the cosine?
14. Show that if $m^2 - n^2$ and $2mn$ be the lengths of the sides respectively of a right-angled triangle, the hypothenuse will be $m^2 + n^2$.

    [Substituting any pairs of numbers for m and n in the expressions in the preceding example will give respectively the sides and hypothenuse of a right triangle. Thus, if $m = 3$, and $n = 2$, the sides will be 5 and 12, and the hypothenuse 13.]
15. Find the relations between the functions for an angle of 45°.

    [Substitute $y = 45°$ in equations (16).]
16. Reduce equations (17) when $y = 45°$.
17. Reduce equations (16) when $y = 90°$.
18. Reduce equations (17) when $y = 90°$.
19. Show that $\sin (90° - \frac{1}{2}y) = \cos \frac{1}{2}y$.
20. $\tan (90° + \frac{1}{4}y) = ?$
21. $\cos (90° - ny) = ?$
22. Given $mx - ny = 90°$, and $\sin ax = \cos by$, to find x and y.

    [From the first of (16) and the second equation of the example, we have

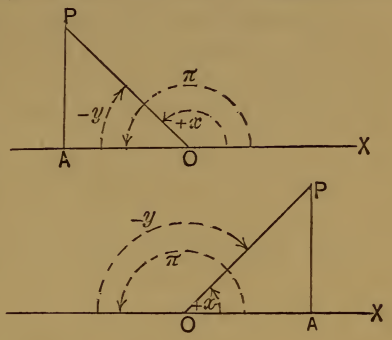
    $$\cos by = \sin (90° - by) = \sin ax;$$

    $$\therefore\ 90° - by = ax.$$

    Hence we find

    $$x = \frac{b + n}{an + bm} 90°,\ y = \frac{m - a}{an + bm} 90°.]$$

27. *Functions of* $180° - y$. In the first of equations (17), making $y = 90° - y_1$, we have for the first member $\sin x = \sin [90° + 90° - y_1)] = \sin (180° - y_1)$; and for the last member $\cos (90° - y_1) = \sin y_1$ [from equations (16)]; hence, dropping subscripts, we have



$$\sin (180° - y) = \sin y.$$

Or, from the figure, we have

$$\sin x = \sin (180° - y) = AP \div OP = o \div r = \sin y,$$

and this relation is true whatever be the value of y.

By means of either of these methods applied to determining the other functions, we find

$$\left.\begin{array}{ll} \sin (180° - y) = \sin y. & \cos (180° - y) = -\cos y. \\ \tan (180° - y) = -\tan y. & \cot (180° - y) = -\cot y. \\ \sec (180° - y) = -\sec y. & \csc (180° - y) = \sec y. \end{array}\right\} (18)$$

The first of these is, *The sine of an angle equals the sine of its supplement.*

The second is, *The tangent of an angle equals* MINUS *the tangent of its supplement.*

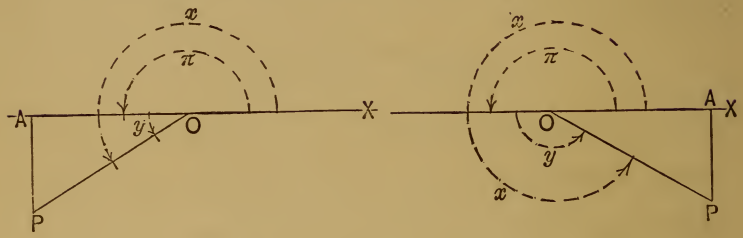
EXERCISES.

1. Construct the angle $180° - y$, when $y > 180°$ and $< 270°$.
2. Construct the angle $180° - y$, when $y > 270°$ and $< 360°$.
3. If $\sin ny^2 = \sin (180° - y)$, find y.
4. If $\cos (90° + ny) = \cos (180° - my)$, find y.

5. Given $\tan(90° + ay) = \cot(180° - by)$, to find y.
   [In this example $y = 0$, or $a = b$.]
6. Is the relation $\tan(180° - y) = \cot(90° - y)$ possible?
7. $\sin(180° - \frac{1}{2}y) = ?$
8. $\cot(180° - \frac{1}{4}y) = ?$

---

28. *Functions of* $(180° + y)$.



Substituting $-y$ for y in equations (18), or from the figure, we find

$$\left.\begin{array}{ll} \sin(180° + y) = -\sin y. & \cos(180° + y) = -\cos y. \\ \tan(180° + y) = \tan y. & \cot(180° + y) = \cot y. \\ \sec(180° + y) = -\sec y. & \csc(180° + y) = -\csc y. \end{array}\right\} (19)$$

29. *Functions of* $(270° \pm y)$.

Making $y = 90° - y$ in equations (19) and reducing by means of equations (16) and (17), we have

$$\left.\begin{array}{ll} \sin(270° \pm y) = -\cos y. & \cos(270° \pm y) = \pm \sin y. \\ \tan(270° \pm y) = \mp \cot y. & \cot(270° \pm y) = \mp \tan y. \\ \sec(270° \pm y) = \pm \csc y. & \csc(270° \pm y) = -\sec y. \end{array}\right\} (20)$$

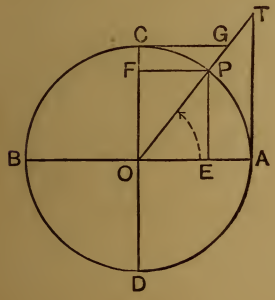
The functions of $n \cdot 360° \pm y$ are the same as for $\pm y$. It will be noticed that the functions of $90° \pm y$, $180° \pm y$. $270° \pm y$, may be expressed as functions of the angle y.

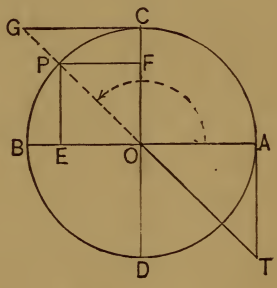
EXERCISES.

1. Construct $270° \pm y$ when $y > 0$ and $< 90°$.
2. Construct $270° \pm y$ when $y > 90 < 180°$.
3. Find the functions of $270° \pm y$ when $y = 45°$.
4. Construct $180° + y$ when $y = -30°$; also if $y = -135°$.
5. Show that $\sin^2(270° \pm y) + \cos^2(270° \pm y) = 1$.
6. Deduce equations (19) directly from the figure.
7. Deduce equations (20) directly from a figure.

TRIGONOMETRICAL LINES.

30. Making r unity in group (B), all the trigonometrical functions may be represented directly by right lines. With a radius $OA = OP = 1$, describe a circum-





ference, and AOP being the angle, draw EP and AT perpendicular to OA, and FP and CG parallel to OA, then

$$\sin AOP = \frac{EP}{OP} = \frac{EP}{1} = EP.$$

$$\cos AOP = \frac{OE}{OP} = \frac{OE}{1} = OE = FP.$$

$$\tan AOP = \frac{AT}{OA} = \frac{AT}{1} = AT.$$

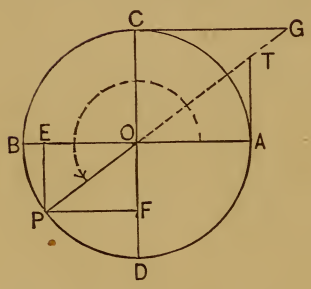
$$\cot AOP = \frac{OA}{AT} = \frac{CG}{OC} = \frac{CG}{1} = CG.$$

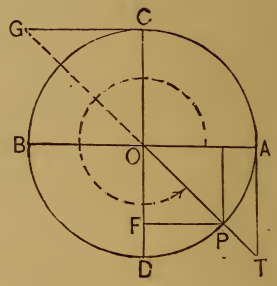
$$\sec AOP = \frac{OT}{OA} = \frac{OT}{1} = OT.$$

$$\csc AOP = \frac{OG}{OC} = OG.$$

$$\text{vrs } AOP = EA.$$

$$\text{cvs } AOP = FC.$$





These results stated as follows are *geometrical* definitions of the trigonometrical functions.

Let A be the origin of the arc, OA the initial radius, OP the terminal side of the angle, C, at a quadrant's distance from A, a secondary origin, and CD a secondary diameter; then in all the figures:

The sine of an arc (or *angle*) *is the perpendicular* FROM *the initial diameter to the terminus of the arc.*

Thus, EP is the sine of the arc AP, positive above BA and negative below.

The cosine of an arc (or *angle*) *is the perpendicular from the secondary diameter to the terminus of the arc.*

Thus, $FP = OE$ is the cosine of the arc AP, positive to the right of CD, and negative to the left.

The trigonometric tangent of an arc (or *angle*) *is that part of the geometric tangent at the origin of the arc limited by the diameter prolonged through the terminus of the arc.*

Thus, AT, drawn tangent to the arc at A, and limited by the diameter through P prolonged, is the trigonometrical tangent of AOP; positive above OA, and negative below.

The cotangent of an arc (or *angle*) *is that part of the geometric tangent at the secondary origin limited by the diameter through the terminus of the arc.*

Thus, CG drawn tangent to the arc at C, and limited by the diameter through P prolonged, is the cotangent of AOP; positive to the right of OC and negative to the left.

The secant of an arc (or *angle*) *is the distance from the centre of the arc to the extremity of the tangent.*

Thus, OT, the distance from the centre O to the extremity T of the tangent AT, is the secant of AOP; positive when the terminus P of the arc is on the secant, negative when P is on the extension of the secant, as in the second and third figures.

The cosecant of an arc (or *angle*) *is the distance from the centre of the arc to the extremity of the cotangent.*

Thus, OG, the distance from the centre O to the extremity G of the cotangent CG, is the cosecant of AOP;

positive when P is on the cosecant, and negative when on its extension.

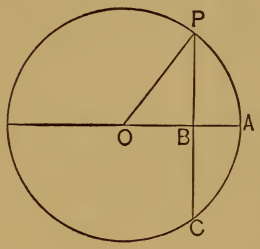
The versed sine of an arc (or *angle*) *is the distance from the foot of the sine to the origin of the arc.*

Thus, EA is the versed sine of the arc AP, and is positive for all real arcs.

The coversed sine of an arc (or *angle*) *is the distance from the foot of the cosine to the secondary origin.*

Thus, FC is the coversed sine of the arc AP, and is positive for all real arcs.

It should be remembered that these lines, in trigonometry, represent ratios—abstract numbers—and not linear quantities.



31. *The sine of an arc equals one-half the chord of double the arc.*

Thus, PB is the sine of the arc AP to the radius unity. But PB is one-half the chord PC of the arc PAC, which is twice the arc PA.

EXERCISES.

1. Find from a geometrical figure the limits of the trigonometrical functions, the values for which have been given on page 16.
2. Construct an angle whose cosine is $\frac{3}{4}$.
   [In the first figure of article 30 take $OE = \frac{3}{4}\ OA$, and erect the perpendicular EP; the radius OP will be the terminus of the required angle].
3. Construct the cosine of an angle whose cotangent is 2.
4. Construct all the trigonometrical functions of an angle whose tangent is -1 and whose sine is negative.

5. Show from a figure by means of similar triangles that $\tan x = \frac{\sin x}{\cos x}$.

Show that the following are true:

6. $\sin 405° = \sin 45°$.
7. $\sin 580° = -\sin 40°$.
8. $\sin 45° > \frac{1}{2} \sin 90°$.
9. $(\sin 60° + \sin 45°) > 1$.
10. $\sin (60° + 45°) < 1$.
11. $\frac{\sin 90°}{\cos 270°} = \infty$.
12. $\frac{\sin 180°}{\cos 90°}$ is indeterminate.
13. $\frac{\sin 360°}{\cos 180°} = 0$.

---

32. If $x = \sin y$, we may write as its equivalent $y = \sin^{-)} x$,* and read it "y equals the arc whose sine is x," or "y equals the angle whose sine is x." †

The several expressions

$$\sin^{-)} x, \quad \tan^{-)} x, \quad \cot^{-)} x, \quad \cos^{-)} x, \text{ \&c.},$$

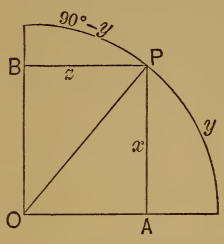
---

* The inverse functions are usually written thus: $\sin^{-1} x$, where 1 is used instead of the curve as in the text. This form is supposed to have been suggested by algebraic expressions like $y = m^{-1} x$; but m^{-1} is a reciprocal, whereas the inverse functions are not reciprocals. The old notation is unfortunate, and has rather been tolerated than approved; and although it is generally better to continue the use of an objectionable notation, especially when in common use, than to introduce a new one, yet, in this case, the modification proposed is so slight and the form is so suggestive of the real nature of the function, we trust it will be approved. The suggestion of its use was made to the author by Professor J. R. Paddock, of the Stevens High School.

† The former reading is sometimes preferred because the terms of the equation are at once strictly homogeneous as line functions. Thus, y being an arc, is linear, and so also is the sine as a geometrical line. The latter, however, is equally correct.

are called *inverse functions, circular functions,* or *anti-functions.*

We will have



$$\sin \sin^{-)} x = x, \quad \sin^{-)} \sin y = y \tag{21}$$

$$\sin \cos^{-)} z = x = \sqrt{1 - z^2}. \tag{22}$$

$$\sin^{-)} \cos y = \sin^{-)} z = 90° - y. \tag{23}$$

Or, more generally,

$$\sin^{-)} \sin y = n\pi + (-1)^n y, \tag{24}$$

where n is an integer, giving n values. But

$$\sin \sin^{-)} x$$

has but one value, and equals x.

33. *The reciprocal* may be indicated in the usual way, by a negative exponent, when no ambiguity results; otherwise a parenthesis should be employed.

Thus,

$$y = \sin \frac{1}{x} = \sin x^{-1}; \tag{25}$$

$$y = \sin^{-)} \frac{1}{x} = \sin^{-)} x^{-1}; \tag{26}$$

$$y = \frac{1}{\cos y} = (\cos y)^{-1} = \cos^{-1} y; \tag{27}$$

but the last form should not be used, for by most writers it designates an inverse function.

$$y = \frac{1}{\sin^{-)} x} = (\sin^{-)} x)^{-1} = \sin^{-)\,-1} x,$$

but the last form had better not be used for the reason just given.

$$y = \tan^{-)} \frac{1}{\cot \frac{1}{y}} = \tan^{-)} (\cot y^{-1})^{-1}.$$

EXERCISES.

1. If $y = \sin^{-)} \frac{2}{3}$, find $\cos y$, and construct a figure showing the several parts.
   [Taking the sine of both members we have $\sin y = \sin \sin^{-)} \frac{2}{3} = \frac{2}{3}$;
   $$\therefore \cos y = \sqrt{1 - \sin^2 y} = \tfrac{1}{3}\sqrt{5}.]$$
2. If $y = \tan^{-)} 3$, find $\sec y$.
3. If $\sin y = \sin^{-)} x$, find x in terms of y and y in terms of x.
   $$Ans.\ x = \sin \sin y, \quad y = \sin^{-)} \sin^{-)} x.$$
   [$\sin \sin y$ is not $\sin^2 y$, but is the sine of an arc whose length equals $\sin y$. Thus $\sin \frac{1}{6}\pi = \sin 30° = \frac{1}{2}$, and $\sin \frac{1}{2}$ is the sine of an arc whose length is one half the radius, or $\frac{1}{2} \times \frac{180°}{\pi} = 29\frac{1}{2}$ degrees nearly.]
4. By means of a figure or by analysis show that $\sin^{-)} x = \csc^{-)} \frac{1}{x}$
   $$= \pm \cos^{-)} \sqrt{1 - x^2} = \pm \sec^{-)} \frac{1}{\sqrt{1 - x^2}} = \pm \tan^{-)} \frac{x}{\sqrt{1 - x^2}}$$
   $$= \pm \cot^{-)} \frac{\sqrt{1 - x^2}}{x}.$$
5. Show that $\sin \tan^{-)} x = \frac{x}{\sqrt{1 + x^2}}$.
6. If $\tan \cos^{-)} x = \sec y$, show that $x = \cos \tan^{-)} \sec y$.
7. If $\sin \cos^{-)} \frac{1}{2} = \cos x$, find $\sin x$.
8. If $\sin^2 y^{\frac{1}{2}} = \cos 0°$, show that $y = \frac{1}{4}\pi^2$
9. If $\sin^{-)} y = \cos^{-)} x$, find y. $Ans.\ y = \sqrt{1 - x^2}$.
10. If $\sin \cos^{-)} \tan y = 0$, show that $y = \frac{1}{4}\pi$.

11. Show that $\sin 30° + \sin 45° > \sin (30° + 45°)$.
12. Show that $\sin 45° + \sin 45° > \sin 90°$.
13. Show that $2 \sin 30° > \sin 2 \times 30°$.
14. Show that $\cos 30° < 2 \cos 60°$.
15. Find the trigonometrical functions of 135°.

[Observe that $135° = 90° + 45°$, and substitute in equations (17). Or, $135° = 180° - 45$, and equations (18) will give the desired solution.]

16. Find the trigonometrical functions of 120°.
17. Given $\sec x = \left[\frac{4 \tan \sin^{-1} \frac{1}{2}}{3 \quad \tan \frac{1}{6}\pi}\right]^{\cos \frac{\pi}{3}}$, to find x.
18. From a geometrical figure similar to those on p. 27, show that the sine of an angle equals the sine of its supplement, or $\sin (180° - x) = \sin x$.
19. Show by means of the figures on page 28, that equations (19) and (20) are true.
20. Prove that $\sin (y - 90°) = -\cos y$.
21. Prove that $\cos (y - 90°) = \sin y$.
22. $\sin (y - 180°) = ?$
23. $\cos (y - 180°) = ?$

---

34. **Multiple angles.** If x be an angle, nx will be an angle n times x, and is called a multiple angle. The general properties of multiple angles will be discussed further on, but the functions of certain multiples of $\frac{1}{2}\pi$ may be readily found in this place.

Thus $\sin (4n + 1) \frac{\pi}{2} = 1$, for all integral values of n;

for the angle will be $(2n\pi + \frac{1}{2}\pi)$ where $2n\pi$ will be n complete circumferences, and $\frac{1}{2}\pi$ added will make n circumferences and 90° more; hence the sine will be the same as $\sin 90°$.

Generally, if n be an integer, either positive or negative, we have

$$\begin{matrix}\sin\\ \cos\end{matrix}\left[2n\frac{\pi}{2}+y\right]=(-1)^n\begin{bmatrix}\sin y\\ \cos y\end{bmatrix} \tag{28}$$

$$\begin{matrix}\sin\\ \cos\end{matrix}\left[(2n+1)\frac{\pi}{2}+y\right]=(-1)^n.\begin{bmatrix}\cos y\\ -\sin y\end{bmatrix} \tag{29}$$

Functions which repeat themselves at regular intervals are called *periodic functions.* Trigonometry may be defined as the algebra of periodic functions.

EXERCISES.

If n be an integer, including 0, show that:

1. $\sin 4n\frac{\pi}{2}=0$; $\sin(4n+2)\frac{\pi}{2}=0$.
2. $\sin(4n+3)\frac{\pi}{2}=-1$; $\cos(4n+2)\frac{1}{2}\pi=-1$.
3. $\tan\frac{1}{2}(2n\pi)=0$; $\cos(4n+1)\frac{1}{2}\pi=0$.
4. $\tan(2n+1)\frac{1}{2}\pi=\pm\infty$; $\cot\frac{1}{2}(2n\pi)=\mp\infty$.
5. $\sin(2n+1)\frac{1}{4}\pi=(+,+,-,-)\frac{1}{2}\sqrt{2}$.

---

35. *Impossible values.* The rules applicable to real functions may be extended to operations upon unreal or imaginary functions. Thus, $\sin x=2$ is impossible according to the definition of the sine, but considering the equation to be true in *fact* as it is in *form*, we have

$$\cos x=\sqrt{1-\sin^2 x}=\sqrt{1-4}=\sqrt{-3}=\sqrt{3}\sqrt{-1}$$

$$\tan x=\frac{\sin x}{\cos x}=-\frac{2}{3}\sqrt{3}\sqrt{-1},$$

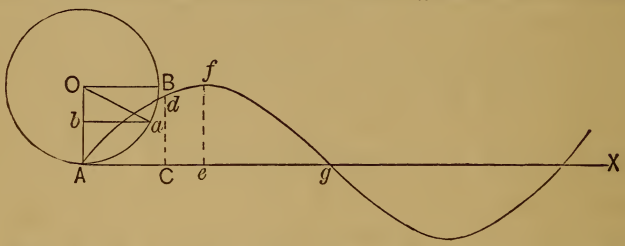
where the imaginary form shows that the original assumption was untrue.

EXERCISES.

1. If sec $x = \frac{1}{2}$, find expressions for all the other trigonometrical functions.
2. If tan $x = \sqrt{-1}$, find expressions for the other trigonometrical functions.
3. If cos $x = 2$, find the other trigonometrical functions.
4. If vsn $x = -1$, find the other functions.
5. Find tan x, given sec $x = \frac{1}{2}$ cos x.
6. Find cos x if sin $x = 2$ tan x.

---

36. The sinusoid. If on the right line AX, there be laid off AC = the arc Aa, Ae = the quadrant AB, and so



on, and at C a perpendicular $Cd = ab$ = the sine of aOA; at e, the perpendicular $ef = BO$ = sin 90°, and so on, and a continuous curve be traced through the ends of the perpendiculars, the curve is called "the sinusoid." The coördinates of its points are expressed by the equation $y =$ sin x, and shows the relation between an arc and its sine. Ag equals a semi-circumference; and the sinusoid will cross the line AX at distances equal to multiples of a semi-circumference.

All the other trigonometrical functions may be represented in a similar way.

EXERCISES.

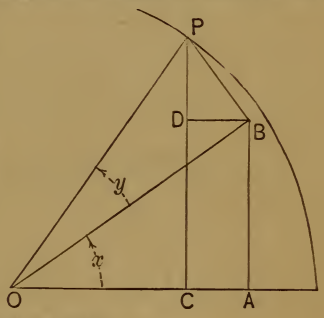
1. Construct a curve representing $y =$ cos x.
2. Construct $y =$ tan x.
3. Construct $y =$ sec x.
4. Construct $y =$ vsn x.

CHAPTER II.

FUNCTIONS OF TWO ANGLES.

37. *To find the sine of the sum and sine of the difference of two angles.*

Let AOB and BOP be two adjacent angles, then will their sum be AOP. From any point P in the terminal line OP, drop the perpendicular PC upon the initial line OA; also PB upon OB, BA upon OA, and BD upon PC. Since PB and PD are perpendicular respectively to the sides OB and OA of the angle AOB, the angle BPD will equal AOB.



Let $x = AOB = DPB$, $y = BOP$; then from the figure and the first of group (B) we have,

$$\sin(x+y) = \frac{CP}{OP} = \frac{CD+DP}{OP} = \frac{AB}{OP} + \frac{DP}{OP}.$$

But,

$$\frac{AB}{OP} = \frac{AB}{OB} \cdot \frac{OB}{OP} = \sin x \cos y,$$

and

$$\frac{DP}{OP} = \frac{DP}{BP} \cdot \frac{BP}{OP} = \cos x \sin y;$$

therefore, $\sin(x+y) = \sin x \cos y + \cos x \sin y.$ (30)

Writing $-y$ for y in this equation, gives

$$\begin{aligned}\sin(x-y) &= \sin x \cos(-y) + \cos x \sin(-y)\\ &= \sin x \cos y - \cos x \sin y. \qquad (31)\end{aligned}$$

Equations (30) and (31) show that—*The sine of the* SUM *of two angles equals the sine of the first into the cosine of the second* PLUS *the cosine of the first into the sine of the second.*

The sine of the DIFFERENCE of two angles equals the sine of the first into the cosine of the second MINUS the cosine of the first into the cosine of the second.

38. *To find the cosine of the sum and difference of two angles.*

From the preceding figure and group (*B*), we have,

$$\cos(x+y) = \frac{OC}{OP} = \frac{OA - CA}{OP} = \frac{OA}{OP} - \frac{DB}{OP}$$

$$= \frac{OA}{OB} \cdot \frac{OB}{OP} - \frac{DB}{PB} \cdot \frac{PB}{OP}$$

$$= \cos x \cos y - \sin x \sin y. \qquad (32)$$

Writing $-y$ for y, gives

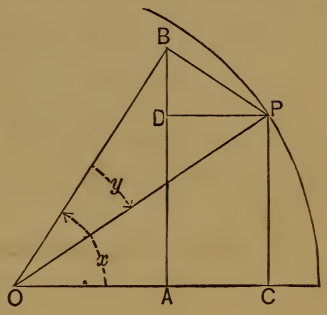
$$\cos(x-y) = \cos x \cos y + \sin x \sin y\,; \qquad (33)$$

that is—*The cosine of the* $\frac{\text{SUM}}{\text{DIFFERENCE}}$ *of two angles equals the product of their cosines* $\frac{\text{MINUS}}{\text{PLUS}}$ *the product of their sines.*

EXERCISES.

1. Represent geometrically the sine and cosine of x and y, and of $x - y$ in a single figure.
2. Deduce equation (31) from a figure.
3. Deduce equation (33) from a figure.
4. Deduce equation (32) from (30) by writing $90° - x$ for x and $-y$ for y.
5. Develop $\sin(a + b + c)$.

   [Let $a + b = x$, then develop $\sin(x + c)$, after which substitute the value of x and continue the development, finding

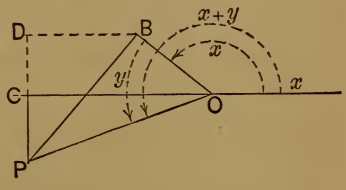


$$\sin(a + b + c) = \sin a \cos b \cos c + \cos a \sin b \cos c + \cos a \cos b \sin c - \sin a \sin b \sin c. \quad (34)$$

6. Show that

$$\cos(x + y + z) = \cos x \cos y \cos z - \sin x \sin y \cos z - \sin x \cos y \sin z - \cos x \sin y \sin z. \quad (35)$$

7. In exercise 6, make $z = 0$ and reduce.
8. In exercise 6 make z negative and reduce.
9. In exercises 5 and 6 make $x = y = z = a = b = c$, and find $\sin 3x$ and $\cos 3x$.
10. Find from a figure $\sin(x + y)$ when $x > 90° < 180°$, and $y > 0 < 90°$, and $x + y < 180°$.
11. Find $\cos(x + y)$ when $x > 90° < 180°$, $y < 90°$, and $x + y > 180°$.



12. Develop $\sin(3x - 2y)$, after which make $x = y$.
13. Given $\sin 45° = \cos 45° = \frac{1}{2}\sqrt{2}$, and $\sin 30° = \frac{1}{2}$, to find sine and cosine of 15°.

    [From equation (3), $\cos 30° = \sqrt{1 - \frac{1}{4}} = \frac{1}{2}\sqrt{3}$; and these several values in (31) and (33), will give $\sin 15° = \frac{1}{4}(\sqrt{6} - \sqrt{2})$, and $\cos 15° = \frac{1}{4}(\sqrt{6} + \sqrt{2})$.]

14. Find sine and cosine of 75°.

[By means of (30) and (32); or by observing that 75° is the complement of 15°, we have $\sin 75° = \cos 15°$, and $\cos 75° = \sin 15°$.]

5. Show that $\sin(45° + y) = \frac{1}{2}\sqrt{2}(\sin y + \cos y)$.
6. Find the sine of $22\frac{1}{2}°$.

[Let $x = y = 22\frac{1}{2}°$ in (32), reducing by means of $\sin^2 22\frac{1}{2}° + \cos^2 22\frac{1}{2}° = 1$, and find $\sin 22\frac{1}{2}° = \frac{1}{2}\sqrt{2 - \sqrt{2}}$.]

17. Find the sine and cosine of $7\frac{1}{2}°$.
18. Develop $\sin(90° - x)$.
19. Develop $\sin^2(x + y)$.
20. Develop $\sin(x + y)^2$.

Prove the following statements:

21. $\cos 75° = \dfrac{\sqrt{3} - 1}{2\sqrt{2}}$.
22. $\sin(A + B) + \sin(A - B) = 2 \sin A \cos B$.
23. $\sin(A + B) - \sin(A - B) = 2 \cos A \sin B$.
24. $\cos(A + B) + \cos(A - B) = 2 \cos A \cos B$.
25. $\cos^4 \varphi - \sin^4 \varphi = \cos 2\varphi$.
26. $\cos(\varphi - 45°) + \sin(\varphi - 45°) = \sqrt{2} \sin \varphi$.
27. $\cos(\varphi - 45°) = \sin(\varphi + 45°)$.
28. $\sin n\varphi \cos \varphi + \cos n\varphi \sin \varphi = \sin(n + 1)\varphi$.
29. $\cos(n - 1)\varphi \cdot \cos \varphi - \sin(n - 1)\varphi \cdot \sin \varphi = \cos n\varphi$.
30. $\sin n\varphi \cos(n - 1)\varphi - \cos n\varphi \cdot \sin(n - 1)\varphi = \sin \varphi$.
31. $\sin 60° + \sin 30° = 2 \sin 45° \cos 15°$.

[Make $60° = 45° + 15°$, and $30° = 45° - 15°$, and develop.]

32. $\sin 3\varphi + \sin 5\varphi = 2 \sin 4\varphi \cos \varphi$.
33. $\cos \frac{1}{3}\pi - \cos \frac{1}{2}\pi = 2 \sin \frac{5}{12}\pi \cdot \sin \frac{1}{12}\pi$.
34. $\sin 2\varphi = 2 \sin \varphi \cos \varphi$.
35. $\cos(60° + \varphi) + \cos(60° - \varphi) = \cos \varphi$.
36. $\sin(\theta + \varphi) \cdot \cos \theta - \cos(\theta + \varphi) \sin \theta = \sin \varphi$.
37. $\sin \varphi = 2 \sin \frac{1}{2}\varphi \cos \frac{1}{2}\varphi$.
38. $\sin \frac{1}{2}\varphi = 2 \sin \frac{1}{4}\varphi \cos \frac{1}{4}\varphi$.
39. $\cos(\alpha + \beta) - \sin(\alpha - \beta) = 2 \sin(45° - \alpha) \cos(45° - \beta)$.
40. Solve the equation $a \sin \varphi + b \cos \varphi = c$.

[Let m and β be two auxiliary quantities determined by the relation

$$m \sin \beta = a.$$
$$m \cos \beta = b;$$

from which we find $\tan \beta = a \div b$, and $m = \sqrt{a^2 + b^2}$.

Substituting in the given equation gives

$$m \sin \beta \sin \varphi + m \cos \beta \cos \varphi = c,$$

or

$$m \cos (\beta - \varphi) = c;$$

$$\therefore \cos (\beta - \varphi) = \frac{c}{m} = \frac{c}{\sqrt{a^2 + b^2}},$$

and

$$\varphi = \beta - \cos^{-1} \frac{c}{\sqrt{a^2 + b^2}}.\Big]$$

41. Find r and φ from the equations

$$r \cos (\varphi + \alpha) = a,$$
$$r \sin (\varphi + \beta) = b.$$

[Expand, multiply the first by $\sin \beta$, the second by $\cos \alpha$, take the difference and find $r \sin \varphi$. Then multiply the first by $\cos \beta$, the second by $\sin \alpha$, add and find $r \cos \varphi$.]

Ans. $\varphi = \tan^{-1} \dfrac{b \cos \alpha - a \sin \beta}{b \sin \alpha + a \cos \beta}$;

$$r = \frac{b \cos \alpha - a \sin \beta}{\cos (\alpha - \beta) \sin \tan^{-1} \dfrac{b \cos \alpha - a \sin \beta}{b \sin \alpha + a \cos \beta}}.$$

42. Given

$$r \cos \varphi \cos \theta = -2,$$
$$r \cos \varphi \sin \theta = +3,$$
$$r \sin \beta \qquad\quad = -4,$$

to find r, φ, θ.

---

39. *Discussion of equations* (30), (31), (32), and (33). Let $x = y$ in (31) and (33), then

$$\sin 0^\circ = \sin x \cos x - \cos x \sin x = 0.$$
$$\cos 0^\circ = \cos x \cos x + \sin x \sin x = \cos^2 x + \sin^2 x.$$

But since x may be any angle, and $\cos 0^\circ$ has but one value, it follows that $\sin^2 x + \cos^2 x = a$ *constant*, and may be taken as unity. Hence, generally,

$$\sin 0^\circ = 0, \qquad \cos 0^\circ = 1.$$

Since 90° is the complement of 0°, we also have

$$\sin 90^\circ = \cos 0^\circ = 1,$$
$$\cos 90^\circ = \sin 0^\circ = 0.$$

Letting $x = y = 90^\circ$ in (30) and (32), we have

$$\sin 180^\circ = \sin 90^\circ \cos 90^\circ + \cos 90^\circ \sin 90^\circ$$
$$= 1 \times 0 + 0 \times 1 = 0,$$

and

$$\cos 180^\circ = \cos 90^\circ \cos 90^\circ - \sin 90^\circ \sin 90^\circ = -1.$$

Let $x = 90^\circ$, then

$$\sin (90^\circ + y) = \sin 90^\circ \cos y + \cos 90^\circ \sin y = \cos y,$$
$$\sin (90^\circ - y) = \sin 90^\circ \cos y - \cos 90^\circ \sin y = \cos y,$$
$$\cos (90^\circ + y) = \cos 90^\circ \cos y - \sin 90^\circ \sin y = -\sin y,$$
$$\cos (90^\circ - y) = \cos 90^\circ \cos y + \sin 90^\circ \sin y = \sin y;$$

the first and third of which have been previously deduced, equations (17), and the second and fourth are in equations (16).

Similarly, if $x = 180^\circ$, we find the functions of the sine and cosine of $180^\circ + x$ and $180^\circ - x$ as given in equations (18) and (19).

Similarly, the functions for $x = 270^\circ$, 360°, $n\frac{\pi}{2}$, $4n\pi$, and any other angles may be found by substituting in the same equations.

Let $x = 0$, then (31) gives

$$\sin(-y) = \sin 0^\circ \cos y - \cos 0^\circ \sin y = -\sin y;$$

and (33) gives

$$\cos(-y) = \cos 0^\circ \cos y + \sin 0^\circ \sin y = \cos y;$$

which are in equations (13) and (14).

Equation (30) may be considered as a *general equation* in this science in the sense that when combined with the definitions of group (*B*) all other equations of trigonometry may be deduced from it.

---

40. *To find the tangent of the sum of two angles, and also of their difference.*

Dividing equation (30) by (32) gives

$$\tan(x+y) = \frac{\sin(x+y)}{\cos(x+y)} = \frac{\sin x \cos y + \cos x \sin y}{\cos x \cos y - \sin x \sin y}$$

$\div$ by $\cos x \cos y$,

$$= \frac{\dfrac{\sin x \cos y}{\cos x \cos y} + \dfrac{\cos x \sin y}{\cos x \cos y}}{1 - \dfrac{\sin x \sin y}{\cos x \cos y}}$$

reducing by means of equations (1) and (2), gives

$$\tan(x+y) = \frac{\tan x + \tan y}{1 - \tan x \tan y}; \qquad (36)$$

that is, *The tangent of the sum of two angles equals the sum of their tangents divided by* 1 MINUS *the product of their tangents.*

Making y negative and reducing by equations (14) gives

$$\tan(x-y) = \frac{\tan x - \tan y}{1 + \tan x \tan y} \qquad (37)$$

41. *To find the cotangent of the sum and difference of two angles.*

Taking the reciprocals of the two preceding equations, we have according to equation (10)

$$\cot(x+y) = \frac{\cot x \cot y - 1}{\cot x + \cot y} \tag{38}$$

$$\cot(x-y) = \frac{\cot x \cot y + 1}{\cot y - \cot x} \tag{39}$$

FUNCTIONS OF DOUBLE THE ARC.

42. Making $x = y$ in (30), (32), (36), and (38), we have

$$\sin 2x = 2 \sin x \cos x \tag{40}$$

$$\cos 2x = \cos^2 x - \sin^2 x \tag{41}$$

$$\tan 2x = \frac{2 \tan x}{1 - \tan^2 x} \tag{42}$$

$$\cot 2x = \frac{\cot^2 x - 1}{2 \cot x} \tag{43}$$

FUNCTIONS OF THE ANGLE IN TERMS OF HALF ANGLE.

43. For x substitute $\frac{1}{2}x$ in (40), (41), (42), and (43), and we have

$$\sin x = 2 \sin \tfrac{1}{2}x \cos \tfrac{1}{2}x \tag{44}$$

$$\cos x = \cos^2 \tfrac{1}{2}x - \sin^2 \tfrac{1}{2}x \tag{45}$$

$$= 1 - 2 \sin^2 \tfrac{1}{2}x \tag{46}$$

$$= 2 \cos^2 \tfrac{1}{2}x - 1 \tag{47}$$

$$\tan x = \frac{2 \tan \frac{1}{2}x}{1 - \tan^2 \frac{1}{2}x}. \tag{48}$$

$$\cot x = \frac{\cot^2 \frac{1}{2}x - 1}{2 \cot \frac{1}{2}x} \tag{49}$$

FUNCTIONS OF ONE-HALF AN ANGLE.

44. From (46) we have

$$\sin \tfrac{1}{2}x = \sqrt{\tfrac{1}{2}(1 - \cos x)} \tag{50}$$

from (47),

$$\cos \tfrac{1}{2}x = \sqrt{\tfrac{1}{2}(1 + \cos x)} \tag{51}$$

(50) ÷ (51),

$$\tan \tfrac{1}{2}x = \sqrt{\frac{1 - \cos x}{1 + \cos x}} \tag{52}$$

(51) ÷ (50),

$$\cot \tfrac{1}{2}x = \sqrt{\frac{1 + \cos x}{1 - \cos x}} \tag{53}$$

(44) ÷ (47),

$$\tan \tfrac{1}{2}x = \frac{\sin x}{1 + \cos x} \tag{54}$$

(44) ÷ (46),

$$\cot \tfrac{1}{2}x = \frac{\sin x}{1 - \cos x} \tag{55}$$

reciprocal (55),

$$\tan \tfrac{1}{2}x = \frac{1 - \cos x}{\sin x} \tag{56}$$

reciprocal (54),

$$\cot \tfrac{1}{2}x = \frac{1 + \cos x}{\sin x} \tag{57}$$

45. From (30), (31), (32), and (33) we obtain by addition and subtraction,

$$\sin(x+y)+\sin(x-y)=2\sin x\cos y \tag{58}$$
$$\sin(x+y)-\sin(x-y)=2\cos x\sin y \tag{59}$$
$$\cos(x+y)+\cos(x-y)=2\cos x\cos y \tag{60}$$
$$\cos(x+y)-\cos(x-y)=-2\sin x\sin y \tag{61}$$

Let $x+y=s$ and $x-y=d$, then $x=\frac{1}{2}(s+d)$, and $y=\frac{1}{2}(s-d)$, which substituted above gives

$$\sin s+\sin d=2\sin\tfrac{1}{2}(s+d)\cos\tfrac{1}{2}(s-d) \tag{62}$$
$$\sin s-\sin d=2\cos\tfrac{1}{2}(s+d)\sin\tfrac{1}{2}(s-d) \tag{63}$$
$$\cos s+\cos d=2\cos\tfrac{1}{2}(s+d)\cos\tfrac{1}{2}(s-d) \tag{64}$$
$$\cos s-\cos d=-2\sin\tfrac{1}{2}(s+d)\sin\tfrac{1}{2}(s-d) \tag{65}$$

which forms are convenient for logarithmic computation.

---

(62) ÷ (63),

$$\frac{\sin s+\sin d}{\sin s-\sin d}=\frac{\tan\frac{1}{2}(s+d)}{\tan\frac{1}{2}(s-d)} \tag{66}$$

(62) ÷ (64),

$$\frac{\sin s+\sin d}{\cos s+\cos d}=\tan\tfrac{1}{2}(s+d) \tag{67}$$

(63) ÷ (64),

$$\frac{\sin s-\sin d}{\cos s+\cos d}=\tan\tfrac{1}{2}(s-d) \tag{68}$$

(62) ÷ (65),

$$\frac{\sin s+\sin d}{\cos s-\cos d}=-\cot\tfrac{1}{2}(s-d) \tag{69}$$

Formula (66) gives,—*The sum of the sines of two angles is to their difference as the tangent of one-half the sum of the angles is to the tangent of one-half their difference.*

EXERCISES.

1. $\tan^{-1}\frac{5}{7} + \tan^{-1}\frac{1}{6} = \frac{1}{4}\pi$.
   [Take tangent of the left member according to equation (36), $\tan(\frac{1}{4}\pi) = 1$.]
2. $\tan^{-1}\frac{1}{2} + \tan^{-1}\frac{1}{3} = \frac{1}{4}\pi$.
3. $\tan^{-1}\frac{1}{5} + \tan^{-1}\frac{2}{3} = \frac{1}{4}\pi$.
4. $\tan^{-1} a + \tan^{-1} b = \tan^{-1}\dfrac{a+b}{1-ab}$.
5. $\sin x = \dfrac{2\tan\frac{1}{2}x}{1+\tan^2\frac{1}{2}x}$.
   [Substitute, $\tan\frac{1}{2}x = \dfrac{\sin\frac{1}{2}x}{\cos\frac{1}{2}x}$.]
6. $\cos x = \dfrac{1-\tan^2\frac{1}{2}x}{1+\tan^2\frac{1}{2}x}$.
7. $\tan\frac{1}{2}x = \dfrac{1+\sin x-\cos x}{1+\sin x+\cos x}$.
8. $\tan(45^\circ \pm y) = \cot(45^\circ \mp y) = \dfrac{\cos y \pm \sin y}{\cos y \mp \sin y}$.
9. $\sin mx = 2\sin(m-1)x\cos x - \sin(m-2)x$.
   [In (58) make $x = (m-1)y$. Another value for $\sin mx$ may be found by making $x = (m-1)y$ in (59).]

   $\therefore \sin 2x = 2\sin x\cos x$

   $\sin 3x = 2\sin 2x\cos x - \sin x = 4\sin x\cos^2 x - \sin x$

   $\sin 4x = 2\sin 3x\cos x - \sin 2x = 8\sin x\cos^3 x - 4\sin x\cos x$.

10. $\cos mx = 2\cos(m-1)x\cos x - \cos(m-2)x$.
    [Deduced from (60). Another value may be found from (61).]

    $\therefore \cos 2x = 2\cos^2 x - 1 = -2\sin^2 x + 1$

    $\cos 3x = 2\cos 2x\cos x - \cos x = 4\cos^3 x - 3\cos x$

    $\cos 4x = 2\cos 3x\cos x - \cos 2x = 8\cos^4 x - 8\cos^2 x + 1$.

11. $\tan 3x = \dfrac{3\tan x - \tan^3 x}{1 - 3\tan^2 x}$.

[Develop $\tan(x + 2x)$ by eq. (36), or make $x = y = z$ in exercise 12.]

12. $\tan(x + y + z) = \dfrac{\tan x + \tan y + \tan z - \tan x \tan y \tan z}{1 - \tan x \tan y - \tan x \tan z - \tan y \tan z}$.

13. Given $\sin x = e^{\sqrt{-1}}$ find $\cos x$.

[$e = 2.718281824 +$, the base of the Naperian system of logarithms.]

14. Given

$$\cos x = \frac{1}{2}\left(e^{x\sqrt{-1}} + e^{-x\sqrt{-1}}\right) \qquad (a)$$

$$-\sin x = \frac{1}{2}\left(e^{x\sqrt{-1}} - e^{-x\sqrt{-1}}\right)\sqrt{-1} \qquad (b)$$

to find $\cos^2 x + \sin^2 x = 1$.

[Equations (a) and (b) are known as *Euler's formulæ*, having been discovered by the celebrated mathematician LEONHARD EULER. They are proved by means of higher analysis, but are placed here for convenience of reference, and to afford an exercise in the use of *imaginaries*. Since they are true for all values of x, they illustrate the fact that *imaginaries* may be so combined as to represent *real* numerical values. One of the most interesting of these simple relations is shown in the mystical combinations given in the next exercise.]

15. In equation (a) of the preceding example, make $x = \frac{1}{2}\pi$ and $i = \sqrt{-1}$, and show that

$$i^{-i} = i^{\frac{1}{i}} = \sqrt[i]{i} = \left[\sqrt{-1}\right]^{\frac{1}{\sqrt{-1}}} = \sqrt{e^{\pi}} = 4.8095 +.$$

16. In De Moivre's formula, which is

$$(\cos\varphi + \sqrt{-1}\sin\varphi)^n = \cos n\varphi + \sqrt{-1}\sin n\varphi,$$

substitute $\varphi = \frac{1}{2}\pi$, and $n = 1, 2, 3$, etc., and reduce, finding the n^{th} powers of $\sqrt{-1}$.

17. By means of equations (*a*) and (*b*), exercise 14, show that

$$\sqrt{-1}\tan x = \frac{e^{2x\sqrt{-1}} - 1}{e^{2x\sqrt{-1}} + 1}.$$

18. Generalizing De Moivre's formula, exercise 16, gives

$$(\cos\varphi + \sqrt{-1}\sin\varphi)^n = \cos n(2r\pi + \varphi) + \sqrt{-1}\sin n(2r\pi + \varphi), \quad (c)$$

where $r = 0, 1, 2, 3$, etc., and n a fraction. By means of this equation the several roots of unity may be found.

What are the three roots of unity? Make $\varphi = 0$, $n = \frac{1}{3}$, and $r = 0, 1, 2$, in eq. (*c*).

Ans. $1, \frac{1}{2}(-1 + \sqrt{-3}), \frac{1}{2}(-1 - \sqrt{-3})$.

19. If $A + B + C = 180°$, we may find

$$\cos A + \cos B + \cos C = 1 + 4\sin\tfrac{1}{2}A \sin\tfrac{1}{2}B \sin\tfrac{1}{2}C$$
$$\sin A + \sin B + \sin C = 4\cos\tfrac{1}{2}A \cos\tfrac{1}{2}B \cos\tfrac{1}{2}C$$
$$\sin 2A + \sin 2B + \sin 2C = 4\sin A \sin B \sin C$$
$$\cos 2A + \cos 2B + \cos 2C = -4\cos A \cos B \cos C - 1$$
$$\tan A + \tan B + \tan C = \tan A \tan B \tan C$$
$$\cot\tfrac{1}{2}A + \cot\tfrac{1}{2}B + \cot\tfrac{1}{2}C = \cot\tfrac{1}{2}A \cot\tfrac{1}{2}B \cot\tfrac{1}{2}C$$
$$\cos\tfrac{1}{2}A + \cos\tfrac{1}{2}B + \cos\tfrac{1}{2}C = 4\cos(45° + \tfrac{1}{4}A)\cos(45° + \tfrac{1}{4}B)\cos(45° + \tfrac{1}{4}C)$$

The following series are readily proved by means of higher mathematics.

20. $$\sin x = \frac{x}{1} - \frac{x^3}{\underline{3}} + \frac{x^5}{\underline{5}} - \frac{x^7}{\underline{7}} + \cdots$$

21. $$\cos x = 1 - \frac{x^2}{\underline{2}} + \frac{x^4}{\underline{4}} - \frac{x^6}{\underline{6}} + \cdots$$

22. $$\sin^{-1} y = y + \tfrac{1}{2}\frac{y^3}{3} + \frac{1 \cdot 3}{2 \cdot 4}\cdot\frac{y^5}{5} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}\cdot\frac{y^7}{7} + \cdots$$

23. $$\sin x = x\left(1 - \frac{x^2}{1^2\pi^2}\right)\left(1 - \frac{x^2}{2^2\pi^2}\right)\left(1 - \frac{x^2}{3^2\pi^2}\right) \cdots \cdots$$

24. $$\cos x = \left(1 - \frac{2^2x^2}{1^2\pi^2}\right)\left(1 - \frac{2^2x^2}{3^2\pi^2}\right)\left(1 - \frac{2^2x^2}{5^2\pi^2}\right) \cdots \cdots$$

25. $$\frac{\pi}{2} = 1 + \frac{1}{2}\cdot\frac{1}{3} + \frac{1}{2}\cdot\frac{1}{4}\cdot\frac{1}{5} + \text{etc.}$$

[By making $y = 1$ in 22d example.]

26. $\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} + \text{etc.}$

27. $\frac{\pi}{4} = 1 - \frac{1}{3}\left(\frac{1}{2}\right)^3 + \frac{1}{5}\left(\frac{1}{2}\right)^5 - \text{etc.}$
$+ \left[\frac{1}{3} - \frac{1}{3}\left(\frac{1}{3}\right)^3 + \frac{1}{5}\left(\frac{1}{3}\right)^5 + \text{etc.}\right].$

28. $\frac{\pi}{2} = \frac{2}{1} \cdot \frac{2}{3} \cdot \frac{4}{3} \cdot \frac{4}{5} \cdot \frac{6}{5} \cdot \frac{6}{7} \cdot \ldots$
which is known as Willis' expression.

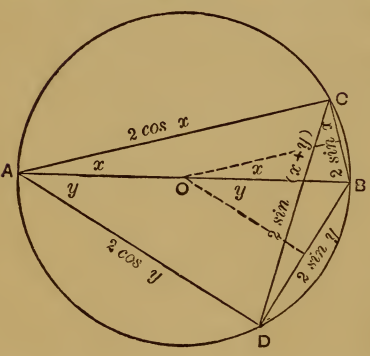
29. $\frac{1}{8}\pi^2 = 1 + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \frac{1}{9^2} + .$ (Todhunter).

30. $\frac{1}{4}\pi^2 = 1 + \frac{1}{3} + \frac{4^2}{3.5.6} + \frac{4^2 . 6^2}{3.5.6.7.8} + \text{etc.}$

31. $(\cos x)^n = 1 - \frac{nx^2}{\underline{|2}} + \frac{n(3n-2)x^4}{\underline{|4}} - \frac{n[15(n-1)^2+1]x^6}{\underline{|6}} + \ldots$

---

46. The following methods will afford some variety in deducing certain expressions.



Let AB be the diameter of a circle whose radius is unity, $BAC = x$, $BAD = y$. Draw CD CB, and BD. Then,

$AC = 2\cos x$, $AD = 2\cos y$,
$CB = 2\sin x$, $DB = 2\sin y$,
$CD = 2\sin(x+y)$,

since the sine of $x + y$ is half the chord of the arc CD. The product of the diagonals of an inscribed quadrilateral equals the sum of the products of its opposite sides, therefore

$$AB \,.\, CD = CB \,.\, AD + AC \,.\, DB$$

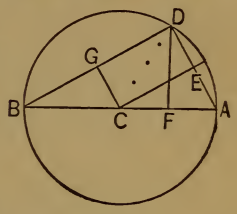
or,

$$2 \times 2\sin(x+y) = 4\sin x\cos y + 4\cos x\sin y$$

which, dropping the common factor 4, gives equation (30).

Constructing a figure with the angles x and y both on the same side of the diameter, the theorem for $\sin(x - y)$ may be as quickly proved in a similar manner.

In the annexed figure let the arc AD, or angle $ACD = x$; draw DB, DA, $CE \perp DA$, $CG \perp BD$; then



$$ACE = ABD = ADF = \tfrac{1}{2}x,$$

$$AE = \sin \tfrac{1}{2}x,\ CE = DG = \tfrac{1}{2}DB = \cos \tfrac{1}{2}x,$$

$$DF = \sin x,\ CF = \cos x,\ BF = 1 + \cos x,\ FA = 1 - \cos x\ ;$$

and

$$\cos \tfrac{1}{2}x = \frac{BF}{BD} = \frac{1 + \cos x}{2 \cos \tfrac{1}{2}x};$$

reducing,

$$2 \cos^2 \tfrac{1}{2}x = 1 + \cos x$$

which is equation (51).

Again

$$\sin \tfrac{1}{2}x = \frac{DF}{BD} = \frac{\sin x}{2 \cos \tfrac{1}{2}x};$$

$$\therefore \sin x = 2 \sin \tfrac{1}{2}x \cos \tfrac{1}{2}x$$

which is equation (44).

Again,

$$\tan \tfrac{1}{2}x = \frac{DF}{BF} = \frac{\sin x}{1 + \cos x}$$

which is equation (51).

Again,

$$\tan \tfrac{1}{2}x = \frac{FA}{DF} = \frac{1 - \cos x}{\sin x}$$

which is equation (56).

Multiplying together the last two equations gives

$$\tan \tfrac{1}{2}x = \sqrt{\frac{1 - \cos x}{1 + \cos x}}$$

which is equation (52).

Again,

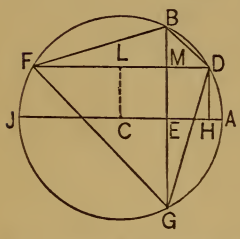
$$\sin \tfrac{1}{2}x = \frac{FA}{DA} = \frac{1 - \cos x}{2 \sin \tfrac{1}{2}x}$$

reducing,

$$\sin^2 \tfrac{1}{2}x = \tfrac{1}{2}(1 - \cos x)$$

which is equation (50).

47. Now constructing another figure, describe a circle with C as a centre, take $AD = y$, $AB = x = AG$; draw FD parallel to the diameter AJ, BEG, and DH perpendicular to AJ, also, FB, BD, DG and FG. Then will the arc $DB = x - y$, the chord



$$BD = 2 \sin \tfrac{1}{2}(x - y), \qquad DH = \sin y$$
$$DG = 2 \sin \tfrac{1}{2}(x + y), \qquad CH = \cos y$$
$$BE = \sin x, \qquad CE = \cos x$$
$$MG = GE + ME = \sin x + \sin y$$

then, since BGD is an angle in the circumference and measured by $\frac{1}{2}BD$,

$$\sin DGM, \text{ or } \sin \tfrac{1}{2}(x - y) = \frac{MD}{GD} = \frac{EH}{GD} = \frac{\cos y - \cos x}{2 \sin \tfrac{1}{2}(x + y)},$$

which gives equation (65).

Again,

$$\tan \tfrac{1}{2}(x - y) = \frac{MD}{MG} = \frac{\cos y - \cos x}{\sin x + \sin y},$$

which is the reciprocal of (69).

Again,

$$\tan DFG = \frac{MG}{FM} = \frac{EG + ME}{LM + FL} = \frac{EG + ME}{LM + LD}$$

or

$$\tan \tfrac{1}{2}(x + y) = \frac{\sin x + \sin y}{\cos x + \cos y}$$

which is equation (67).

Again,

$$\tan \tfrac{1}{2}(x - y) = \frac{BM}{FM} = \frac{\sin x - \sin y}{\cos x + \cos y}$$

which is equation (68).

Again,

$$\frac{\tan \tfrac{1}{2}(x + y)}{\tan \tfrac{1}{2}(x - y)} = \frac{MG}{MB} = \frac{\sin x + \sin y}{\sin x - \sin y},$$

which is equation (66).

We have

$$FGB = 90° - GFM = 90° - \tfrac{1}{2}(x + y);$$
$$\therefore FB = 2 \sin (FGB) = 2 \cos \tfrac{1}{2}(x + y).$$

Then

$$\sin BFD, \text{ or } \sin \tfrac{1}{2}(x - y) = \frac{BM}{FB} = \frac{\sin x - \sin y}{2 \cos \tfrac{1}{2}(x + y)}$$

which gives equation (63).

---

48. *Construction of tables.* Since the student is not expected to make trigonometrical tables, we will only state briefly how they may be made. To make a table of sines, find the length of arc for the required angle, the radius being unity, and substitute in the second member of example 20, page 49, and reduce. Thus, to find the sine of 10°, the arc will be $x = \frac{\pi}{180} \times 10 = 0.1745329$, which substituted in example 20, above referred to, and reduced will give $\sin 10° = 0.17365 +$. In this, or in some other way, the sine of all angles differing by 1′, and in some cases by 1″, have been computed and entered in a table. Then $\cos x = \sqrt{1 - \sin^2 x}$ gives the cosines, tan = sin ÷ cos gives the tangents, and cot = 1 ÷ tan, the cotangents. A table containing these values, is called a table of *natural* trigonometrical functions. The term *natural* is used to distinguish them from logarithmic functions.

A table of logarithmic trigonometrical functions consists of the logarithms of the functions increased by 10. Thus, $\sin 10° = 0.17365$, and $\log \sin 10° = \log 0.17365 = \bar{1}.239670$. Adding 10, we have 9.239670, and this number is entered in the table as log sin 10°. The number 10 is added to avoid negative characteristics. For directions for using the tables, see description just preceding the tables used.

CHAPTER III.

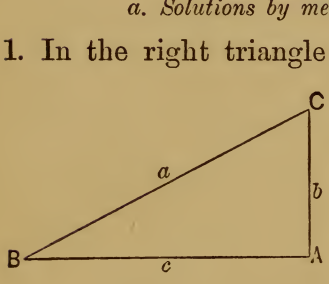
SOLUTION OF PLANE TRIANGLES.

49. Right angled triangles. The formulas in group (*A*) are directly applicable to the solution of right triangles. The parts of a triangle are its sides and angles.

EXAMPLES.

a. Solutions by means of Natural Functions.

1. In the right triangle BAC, if the angle $B = 43° 25' 18''$, and the hypothenuse $BC = 235$, find the remaining parts.



To find C. Since the three angles of a triangle $= 180°$, and $A = 90°$, therefore $B + C = 90°$, and $C = 90° - B$; hence C is the complement of B; and $C = 90° - 43° 25' 18'' = 46° 34' 42''$.

To find BA. From group (*A*) we have

$$\cos B = \frac{\textit{side adjacent}}{\textit{hypothenuse}} = \frac{BA}{BC} = \frac{c}{a};$$

By means of a table of natural cosines, we find $\cos 43° 25' = 0.72637$. To find it for $18''$ more, we assume that the function varies directly as

the angle for $1'$ — which, though not exact, is sufficiently so for ordinary practice. From the same table, $\cos 43^\circ 26' = 0.72617$, hence, $0.72637 - 0.72617 = 0.00020$ is the decrease in the cosine for $1' = 60''$; hence for $18''$ the decrease will be $\frac{18}{60}$ of $0.00020 = 0.00006$, and this subtracted from the $\cos 43^\circ 25'$, gives

$$\cos 43^\circ 25' 18'' = 0.72631;$$
$$\therefore BA = 235 \times 0.72631 = 170.68 +$$

To find the natural sine, the difference for the seconds must be *added* to the sine of the degrees and minutes of the smaller angle.

To find AC. From group (*A*) we have

$$\sin B = \frac{AC}{BC} = \frac{b}{a};$$
$$\therefore AC = a \sin B = 235 \times \sin 43^\circ 25' 18''$$
$$= 235 \times 0.68736 = 161.5296.$$

Collecting results, we have

Ans. $C = 46^\circ 34' 42''$
$BA = 170.68$
$AC = 161.5296.$

[It is generally advisable to compute all the known parts from the given ones, so that if an error is made in determining one of the parts it will not affect the computation of the other parts.]

Check. As a *check* upon the work some of the computed parts may be determined by involving some of the other computed parts. Thus, having found the angle C and the side b, we have

$$c = a \sin C = b \tan C.$$

Also

$$a^2 = b^2 + c^2.$$

2. In the right angled triangle BAC the angle B is $33° 30'$ and the side AC is 52.21. Find the other parts.

Ans. $BC = 94.6$; $AB = 78.88$; $C = 56° 30'$.

3. In the right angled triangle BAC the hypothenuse BC is 127.9 and the side CA is 97.72, to find the other parts.

Ans. $B = 49° 49' 15''$; $BA = 82.51$; $C = 40° 10' 45''$.

4. In the right angled triangle DEF, given the side EF 75, and the side DE 50.59, to find the other parts.

5. Given one of the acute angles $44°$, and the hypothenuse 405, to find the other parts.

6. In a right angled triangle one of the acute angles is $67° 0' 25''$ and the side opposite is 710, to find the other parts.

b. Solution by Means of Logarithmic Functions.

7. Given $a = 672.3412$, $B = 35° 16' 25''$, to find the other parts.

To find b. We have from group (*A*),

$$\sin B = \frac{b}{a};$$

$$\therefore b = a \sin B;$$

$$\therefore \log b = \log a + \log \sin B.$$

Add the logarithmic sine of B as found from the table of logarithmic functions, to the logarithm

of a, then will the number corresponding to the sum of the logarithms be the required number. The work may be arranged thus:

$a = 672.3412 \ldots\ldots\ldots \log 2.827590$
$B = 35° 16' 25'' \ldots\ldots \log \sin 9.761538$
$\therefore\ b = 388.264 \ldots\ldots\ldots\ldots \log 2.589128$

Ten has been dropped from the characteristic because the tabular logarithmic sine is ten too large. Finally, 388.264 is the number corresponding to the logarithm 2.589128.

To find c. We have $\cos B = \frac{c}{a}$;

$\therefore \log c = \log a + \log \cos B.$
$a = 672.3412 \ldots\ldots\ldots \log 2.827590$
$B = 35° 16' 25'' \ldots\ldots \log \cos 9.911905$
$c = 548.902 \ldots\ldots\ldots\ldots \log 2.739495$

To find C. We have $C = 90 - 35° 16' 25'' = 54° 43' 35''$.

Ans. $\begin{cases} b = 388.264 \\ c = 548.902 \\ C = 54° 43' 35'' \end{cases}$

Check. To test the accuracy of the work, compute the same quantity by different formulas.

Thus, we have $c = a \sin C$;
$\therefore \log c = \log a + \log \sin C$;
or
$\tan B = \frac{b}{c}$;
$\therefore \log \tan B = \log b - \log c.$

If the last formula be used, employing the computed values of b and c, and the value thus found for B agrees with that given in the example, it is very certain that not only are the values of b and c correct, but also the process of verification. They will be absolutely correct if there are no errors balancing each other.

8. Given the hypothenuse 65.07 and one of the acute angles 39° 38′ 28″, to find the other parts.

Ans. 41.51; 50.11; 50° 21′ 32″.

9. Given the hypothenuse 2195 and acute angle 27° 38′ 50″, to find the other parts.

10. Given the hypothenuse 365 and one side 86, to find the other parts.

Ans. 13° 37′ 41″; 76° 22′ 19″; 354.724.

11. Given the hypothenuse 0.897 and one of the sides 0.00086, to find the other parts.

Ans. 3′ 17″.7; 89° 56′ 42″.3; 0.89538.

[To find an angle less than 2° from the logarithmic table, see EXPLANATION OF THE TABLES.]

12. Given the hypothenuse 672.3 and one of the sides 548.9, to find the other parts.

Ans. 35° 17′; 54° 43′; 388.2.

13. In a right angled triangle given one of the sides 7643.5 and the angle opposite 37° 18′, to find the other parts.

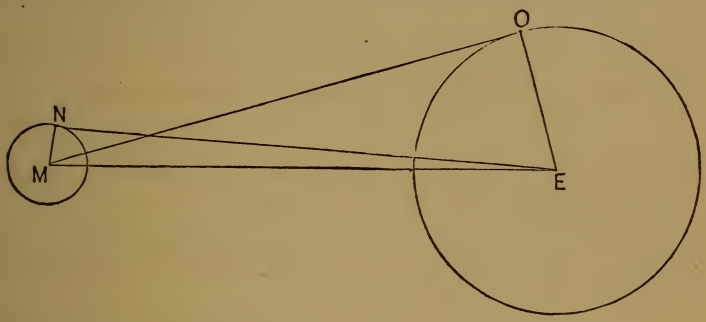
14. Given the two sides 1728 and 1575, to find the other parts.

15. Given the two sides 246.32 and 380.07, to find the other parts.

16. In the figure if M represents the moon and EO the earth, the radius of the earth $EO = 3956.2$ miles,

and the angle $OME = 57'$, required the distance ME, O being a right angle.

$ME = 238{,}614$ miles.



17. If EN is a tangent to the moon's disc at N, the angle NEM will be the moon's apparent semi-diameter. The apparent diameter of the moon being $31'\ 20''$, and the distance from the earth as found in the last example, what is the diameter of the moon?

Ans. 2174.8 miles.

18. A tower 150 feet high throws a shadow 75 feet long upon the horizontal plane of its base; what is the angle of elevation of the sun?

19. A railroad track makes a vertical rise of 150 feet in a distance of 3,000 feet, by uniform grade. What is the angle of the grade?

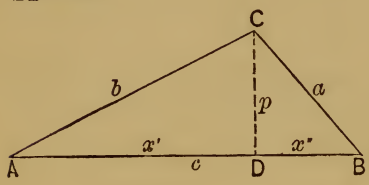
20. A rope whose length is 109 feet is fastened to the top of a tower 60 feet high, the lower end being carried as far as possible from the foot of the tower and fastened to the ground, required the angle which it makes with the horizon.

21. Given the earth's equatorial radius 3962.8 miles, and the sun's horizontal parallax 8″.87, find the distance of the earth from the sun.

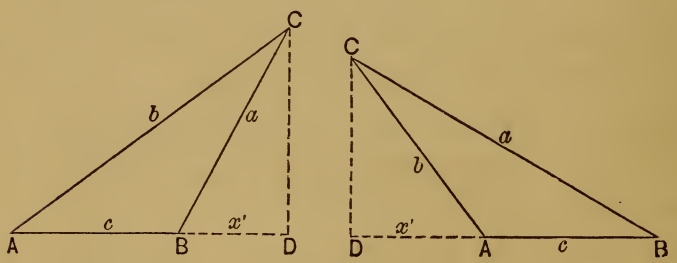
[The sun's horizontal parallax is what the apparent radius of the earth would appear to be if viewed from the centre of the sun.] *Ans.* 92,152,000 miles.

OF OBLIQUE ANGLED PLANE TRIANGLES.

50. **A general relation.** *The ratio of any two sides of a plane triangle equals the ratio of the sines of the angles opposite.*



Let ABC be any plane triangle the angles of which are denoted by A, B, C, and the sides opposite by a, b, c, respectively. From any angle C let fall the perpendicular p upon the opposite side, or that side prolonged if necessary.



From the right triangle ADC we have

$$\sin A = \frac{p}{b},$$

and from BDC

$$\sin B = \frac{p}{a},$$

and dividing the former by the latter, cancelling p, we have

$$\frac{\sin A}{\sin B} = \frac{a}{b}. \tag{70}$$

Similarly,

$$\frac{\sin A}{\sin C} = \frac{a}{c}, \tag{71}$$

which was to be proved.

Generally,

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C}. \tag{72}$$

The common value of this ratio is sometimes called *the modulus* of the triangle.

---

51. **Case I.** *Given two angles and one side.*
Let b be the side, A and B the angles.

Then

$$C = 180^\circ - (A + B), \tag{73}$$

and (71),

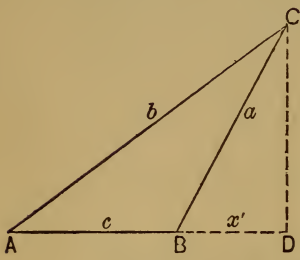
$$a = c\frac{\sin A}{\sin C}, \tag{74}$$

and (72),

$$c = b\frac{\sin C}{\sin B} \tag{75}$$

EXAMPLES.

1. In the triangle ABC, let $A = 48° 3'$, $C = 40° 14'$, and and $AC = 376$, to find the other parts,



From (73)

$$B = 91° 43'$$

To find c, use (75), as follows :

$B = 91° 43'$ ar. co.	log sin 0.000195
$C = 40° 14'$	log sin 9.810167
$b = 376$	log 2.575188
$\therefore\ c = 243$	log 2.385550

(The log sin 91° 43′ is the same as log cos 1° 43′.)

To find $BC = a$, use (74), and find $a = 279.8$.

Ans. $B = 91° 43'$, $a = 279.8$, $c = 243$.

2. In the triangle ABC, let $A = 10° 12'$, $B = 96° 36'$, and $BC = 5.55$, to find the other parts.

3. In the triangle ABC, let $A = 81° 30' 10''$, $B = 40° 30' 44''$ and $AB = 696$, to find the other parts.

4. In the triangle ABC, let $A = 68° 4' 20''$, $B = 56° 32', 35''$, and $AC = 696.75$, to find the other parts.

---

52. **Case II.** *Given two sides and angle opposite one of them.*

Let a, b, B, be the given parts.

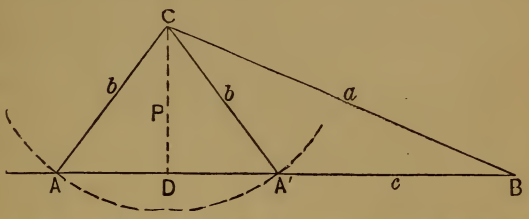
To find A. From (72) we have

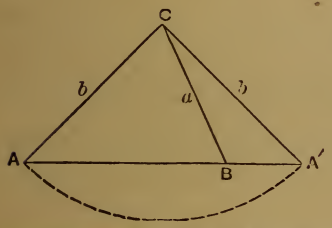
$$\sin A = \frac{a}{b} \sin B. \qquad (76)$$

But since the angle A and its supplement have the same sine, there will generally be two angles found by (76) which will fulfil the conditions of the problem, and

hence two triangles, BAC and $BA'C$, and the result is said to be *ambiguous*. The several conditions involved in this case are most readily discussed geometrically.

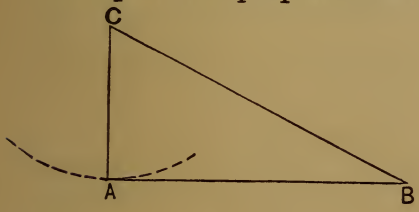
Thus, to construct the triangle, at B draw the lines BC and BA making $ABC = B$. On BC take the distance a, and with C as a centre and radius $CA = b$ describe an arc AA', and if it cuts BA in two points on the same side of B there will be two triangles.

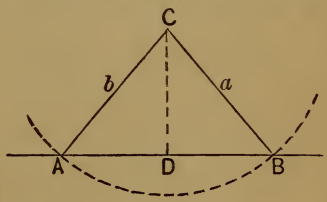




If $b > a$ there will be only one triangle. For if B is acute the triangle will be ABC, but if B is obtuse the triangle will be $BA'C$. Both triangles are not admissible for the same data.

If b equals the perpendicular from C to BA, and B is

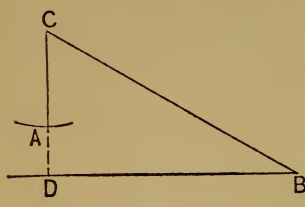




acute, there will be one triangle. But if B be obtuse there will be no triangle.

If $b = a$ and B is acute, there will be one triangle, ABC. But if $b = a$ and B is obtuse, or right, there will be no triangle, for b and a will coincide.

If B is acute, right, or obtuse, and b is less than the perpendicular from C to BD, there will be no triangle.



If there be two triangles, represent the two angles found by A' and A'', and the two sides by c' and c''.

EXAMPLES.

1. Given $a = 31.238$, $b = 49$, and $A = 32° 18'$, to find B, C, and c.

To find B. Eq. (76)

$a = 31.238$..... ar co log 8.505316
$b = 49$..... log 1.690196
$A = 32° 18'$..... log sin 9.727828

$\therefore B' = 56° 56' 57''$.. log sin 9.923340
$B'' = 123° 3' 3''$

To find C′ and C″.

$C' = 180° - (32° 18' + 56° 56' 57'') = 90° 45' 3''$
$C'' = 180° - (32° 18' + 123° 3' 3'') = 24° 38' 57''$

To find c′ and c″.

$C' = 90° 45' 3''$.....log sin 9.999996
$C'' = 24° 38' 57''$..... log sin 9.620196
$A = 32° 18'$ " ar co log sin 0.272172.....0.272172
$a = 31.238$.....log 1.494693.....1.494693

$\therefore c' = 58.460$.....log 1.766862
$c'' = 24.381$..... 1.387062

Ans. $\left\{\begin{matrix} B' = 56° 56' 57'' \\ C' = 90° 45' 3'' \\ c' = 58.460 \end{matrix}\right\}$ or $\left\{\begin{matrix} B'' = 123° 3' 3'' \\ C'' = 24° 38' 57'' \\ c'' = 24.381 \end{matrix}\right\}$

2. In the triangle ABC, let $BC = 94.26$, $AC = 126.2$ and $A = 27° 50'$, to find the other parts.

$B = 38° 52' 46''$. $C = 113° 17' 14''$. $c = 185.439$.
or $141° 7' 14''$. $11° 2' 46''$. 39.682.

3. Given $a = 91.06$, $b = 77.04$, $A = 51° 9' 6''$. Find the other parts.

$B = 41° 13'$; $C = 87° 37' 54''$; $c = 116.82$.

4. Given $a = 1257.5$, $c = 1751$, $A = 31° 17' 19''$. Find the other parts.

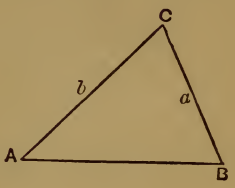
5. Given $a = 40$, $b = 55$, $A = 60°$. *Ans. Impossible.*

6. Given $a = 43$, $b = 45$, $A = 120°$. *Ans. Impossible.*

---

53. **Case III.** *Given two sides and the included angle.*

Let a, b, C, be the given parts.



From (70) we have

$$\frac{a}{b} = \frac{\sin A}{\sin B}$$

Adding one to both members, we have by reduction,

$$\frac{a+b}{b} = \frac{\sin A + \sin B}{\sin B}.$$

Similarly, subtracting 1 from both members,

$$\frac{a-b}{b} = \frac{\sin A - \sin B}{\sin B}.$$

Dividing gives,

$$\frac{a+b}{a-b} = \frac{\sin A + \sin B}{\sin A - \sin B}.$$

This reduced by (66) gives

$$\frac{a+b}{a-b} = \frac{\tan \frac{1}{2}(A+B)}{\tan \frac{1}{2}(A-B)}; \tag{77}$$

that is, *The sum of two sides of a plane triangle is to their difference, as the tangent of half the sum of the angles opposite is to the tangent of half their difference.*

To find $A + B$ *we have*

$$A + B = 180^\circ - C. \tag{78}$$

To find $A - B$ *we have from* (77) *and* (78)

$$A - B = 2 \tan^{-1}\left[\frac{a-b}{a+b} \tfrac{1}{2} \tan (180^\circ - C)\right] \tag{79}$$

Reducing the quantity in the brackets, [ ], and finding the angle corresponding to this tangent by means of a table of trigonometrical functions, and multiplying the result by 2 will give $A - B$.

To find A *and* B. We have from (78) and (79)

$$A = \tfrac{1}{2}[(A+B) + (A-B)] \tag{80}$$

$$B = \tfrac{1}{2}[(A+B) - (A-B)] \tag{81}$$

To find c. We have from (71)

$$c = \frac{\sin C}{\sin A} a \tag{82}$$

A solution may also be made by means of right triangles, as will be shown in article 55.

EXAMPLES.

1. In a plane triangle ABC, given $a = 748$, $b = 375$, $C = 63^\circ\ 35'\ 30''$, to find the other parts of the triangle.

$a + b = 1123$ a. c. log 6.949620
$a - b = 373$ log 2.571709
$\frac{1}{2}(A + B) = 58° 12' 15''$ log tan 10.207660
$\therefore \frac{1}{2}(A - B) = 28° 10' 54''$ log tan 9.728989
$A = 86° 23' 9''$
$B = 30° 1' 21''$ ..... a. c. log sin 0.300744
$C = 63° 35' 30''$ ..... log sin 9.952137
$b = 375$ ..... log 2.574031
$c = 671.29$ ..... log 2.826912

Ans. $A = 86° 23' 9''$, $B = 30° 1' 21''$, $c = 671.29$.

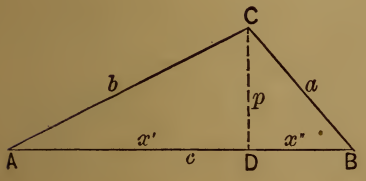
2. Given $c = 304$, $a = 280.3$ $B = 100°$, to find the other parts.
Ans. $A = 38° 3' 33''$, $C = 41° 56' 57''$, $b = 447.86$.

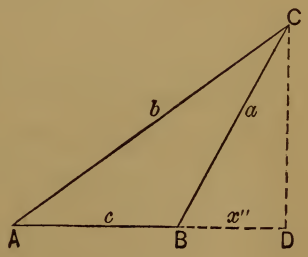
3. Given $a = 468$, $b = 365$, $C = 82° 22' 22''$, to find the other parts.

4. Given $a = .3756$, $b = .2375$, $C = 68° 25'$, to find the other parts.

---

54. **Case IV.** *Given the three sides of a triangle, to find the angles.*





From the figure we have

$$AD = x' = b \cos A, \quad DB = x'' = a \cos B,$$

$$\left.\begin{aligned} \therefore\ x' + x'' &= c = b\cos A + a\cos B \\ \text{similarly,}\quad b &= a\cos C + c\cos A \\ a &= c\cos B + b\cos C \end{aligned}\right\} \tag{83}$$

In the second figure $\cos B$ is negative; hence x'' will be negative, and we have

$$\begin{aligned} c = x' + (-x'') &= x' - x'' = b\cos A - a(-\cos B) \\ &= b\cos A + a\cos B \end{aligned}$$

as before.

From the 1st of (83),

$$a\cos B = c - b\cos A$$

squaring, $a^2\cos^2 B = c^2 - 2bc\cos A + b^2\cos^2 A$,

from (72) $a^2\sin^2 B = b^2\sin^2 A$,

adding,

$$\left.\begin{aligned} a^2 &= c^2 + b^2 - 2bc\cos A \\ \text{similarly,}\quad b^2 &= a^2 + c^2 - 2ac\cos B \\ c^2 &= a^2 + b^2 - 2ab\cos C \end{aligned}\right\} \tag{84}$$

From (84) we have

$$\left.\begin{aligned} \cos A &= \frac{-a^2 + b^2 + c^2}{2bc} \\ \cos B &= \frac{a^2 - b^2 + c^2}{2ac} \\ \cos C &= \frac{a^2 + b^2 - c^2}{2ab} \end{aligned}\right\} \tag{85}$$

Equations (85) will solve this case by means of natural functions. To adapt them to logarithmic computation, they may be transformed thus:

Subtracting each member of the first of (85) from unity we have

$$\begin{aligned} 1 - \cos A &= \frac{2bc + a^2 - b^2 - c^2}{2bc} = \frac{a^2 - (b-c)^2}{2bc} \\ &= \frac{(a + b - c)(a - b + c)}{2bc}. \end{aligned}$$

But $1 - \cos A = 2 \sin^2 \frac{1}{2}A$ (eq. (50)); and letting $2s = (a + b + c)$, we have $a + b - c = 2(s - c)$, and $a - b + c = 2(s - b)$; hence

$$\sin^2 \tfrac{1}{2}A = \frac{(s-b)(s-c)}{bc};$$

$$\left.\begin{aligned} \therefore \sin \tfrac{1}{2}A &= \sqrt{\frac{(s-b)(s-c)}{bc}} \\ \text{similarly,} \quad \sin \tfrac{1}{2}B &= \sqrt{\frac{(s-a)(s-c)}{ac}} \\ \sin \tfrac{1}{2}C &= \sqrt{\frac{(s-a)(s-b)}{ab}} \end{aligned}\right\} \quad (86)$$

Adding each member of (85) to unity, and reducing in a similar manner, we find

$$\left.\begin{aligned} \cos \tfrac{1}{2}A &= \sqrt{\frac{s(s-a)}{bc}} \\ \cos \tfrac{1}{2}B &= \sqrt{\frac{s(s-b)}{ac}} \\ \cos \tfrac{1}{2}C &= \sqrt{\frac{s(s-c)}{ab}} \end{aligned}\right\} \quad (87)$$

Dividing each of equations (86) by the corresponding one of (87), gives

$$\left.\begin{aligned} \tan \tfrac{1}{2}A &= \sqrt{\frac{(s-b)(s-c)}{s(s-a)}} \\ \tan \tfrac{1}{2}B &= \sqrt{\frac{(s-c)(s-a)}{s(s-b)}} \\ \tan \tfrac{1}{2}C &= \sqrt{\frac{(s-a)(s-b)}{s(s-c)}} \end{aligned}\right\} \quad (88)$$

EXAMPLES.

1. In a plane triangle, given $a = 30$, $b = 25$, and $c = 20$, to find the angles.

By natural functions. The first of equations (85) gives

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc} = \frac{625 + 400 - 900}{1000} = 0.125,$$

hence

$$A = 82^\circ\ 49'\ 9''.$$

In a similar manner the values of B and C may be found.

2. In a plane triangle $a = 21.35$, $b = 12.17$, $c = 10.08$, to find the angles.

By logarithmic functions. Using equations (88),

		log		log.		log
$s = 21.80$	a. c.	8.661544	a. c.	8.661544	a. c.	8.661544
$s - a = 0.45$	a. c.	10.346787		$\bar{1}$.653213		$\bar{1}$.653213
$s - b = 9.63$		0.983626	a. c.	9.016374		0.983626
$s - c = 11.72$		1.068928		1.068928	a. c.	8.931072
		2)1.060885				
$\frac{1}{2}A = 73^\circ\ 34'\ 25''$....	tan	0.530442		2)18.400059		
$\frac{1}{2}B = 9^\circ\ 0'\ 22.''5$.....	tan	9.200029				2)$\bar{2}$.229455
$\frac{1}{2}C = 7^\circ\ 25'\ 12.''5$.....	tan	9.114727				

Ans. $A = 147^\circ\ 8'\ 50''$ $B = 18^\circ\ 0'\ 45''$ $C = 14^\circ\ 50'\ 25''$.

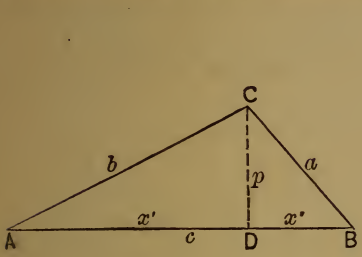
3. Given $a = 14$, $b = 17$, $c = 19$, to find the angles.

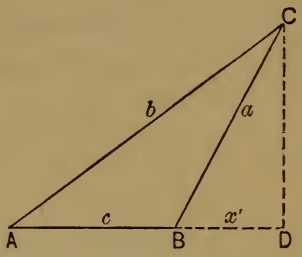
4. Given $a = 0.0237$, $b = 0.164$, $c = 0.0843$, to find the angles.

---

55. *Solution by means of right triangles.* Let ABC be any plane triangle, CD a perpendicular from any angle

C upon the opposite side AB. We may indicate briefly the solutions for the several cases.





Case I. *Given one side and two angles.*

Let $AC = b$, be the side, A and C the angles, then

$$B = 180° - (A + C); \quad BCD = 90° - B;$$
$$ACD = 90° - A, \qquad (89)$$

$$AD = b \cos A = x'; \quad CD = b \sin A = p;$$
$$CB = CD \div \cos BCD = a; \qquad (90)$$

$$DB = a \cos B = x''; \quad \therefore AB = x' + x''; \qquad (91)$$

observing that x'' in the second figure will be negative, since cos B will be negative.

Case II. *Given two sides and an angle opposite one of them.*

Let a and b be the sides and A the angle. Find AD and CD as in Case I. Then sin $B = p \div a$; $C = 180° - (A + B)$; $BD = a \cos B$; hence all the parts will be found.

Since B generally has two values in the equation sin $B = p \div a$, there will generally be two solutions.

Case III. *Given two sides and the included angle.*

Let the given parts be b, c, A. Find $AD = x'$, and $CD = p$ as in Case I. Then $DB = c - x' = x''$; tan $B = p \div x''$; $DCB = 90° - B$; $ACD = 90° - A$

$\therefore ACB = 90° - (A + B)$, and all the parts become known.

Case IV. *Given the three sides.*

Let $CD = p$, $AD = x'$, $BD = x''$; then

$$p^2 = b^2 - x'^2 = a^2 - x''^2,$$

and

$$x' + x'' = c,$$

These equations give

$$x' = \frac{-a^2 + b^2 + c^2}{2c} \qquad x'' = \frac{a^2 - b^2 + c^2}{2c} \tag{92}$$

Then

$$\cos A = \frac{x'}{b} \qquad \cos B = \frac{x''}{a}; \tag{93}$$

in which if x' or x'' be negative, the corresponding angle will be obtuse. The angle C may be found by dropping a perpendicular from A or B and proceeding as before; or, simply, $C = 180° - (A + B)$.

EXAMPLES.

1. Given $a = 250$ $A = 10° 12$ $B = 46° 36'$
   find $C = 123° 12'$ $c = 1181.30$ $b = 1025.74$
2. Given $a = 17.432$ $b = 19\,574$ $A = 38° 44' 12''$
   find $c' = 27.908$ $B' = 44° 1' 28''$ $C' = 97° 44' 30''$
   $c'' = 2.8404$ $B'' = 135° 58' 32''$ $C'' = 5° 47' 16''$
3. Given $a = 95.98$ $b = 66.28$ $C = 175° 19' 10''$
   find $A = 2° 46' 8''$ $B = 1° 54' 42''$ $c = 162.128$
4. Given $a = 6$, $b = 8$, $c = 10$; find the angles.

5. Given $a = 15$, $b = 15$, $c = 17$; find the angles.
6. Given $a = \sqrt{-2}$, $b = \sqrt{-3}$, $c = \sqrt{-7}$; find the angles.
7. Given $a = 3\sqrt{-1}$, $b = 4\sqrt{-1}$, $B = 60° 38'$, to find the other parts.

---

56. **Small angles.** For tables which give the values of the trigonometrical functions to minutes only, the student is obliged to compute the values for the seconds. This is usually done by assuming that the function varies directly as the angle from minute to minute. But for angles less than two degrees and near 90°, this is not sufficiently exact; hence these angles should be avoided, if possible, unless special tables are provided, which either give the values of the functions to seconds, or which give the means of computing the values of the small angles more accurately. In this work, the latter plan is adopted, as may be seen by consulting the first two pages of the table of logarithmic trigonometrical functions.

In this case the values of

$$\log \frac{\sin x}{x} = \log \sin x - \log x = q - l \qquad (94)$$

$$\log \frac{\tan x}{x} = \log \tan x - \log x = q - l \qquad (95)$$

are computed for each minute, and change slowly, as may be seen by examining the table, where even the sixth figure, in some cases, is the same for several *minutes* of arc. If the angle be given in seconds, we have

$$\sin x = x'' \frac{\sin x}{x}; \tag{96}$$

$$\therefore \log \sin x = \log x'' + q - l, \tag{97}$$

or $$\log x'' = \log \sin x - (q - l) \tag{98}$$

Similarly, $$\log \tan x = \log x'' + (q - l);$$

$$\therefore \log x'' = \log \tan x - (q - l), \tag{99}$$

where $q - l$ in the latter case is taken from the column next to that for tangents.

EXAMPLE. Given the base of a right triangle 4500 and altitude 5, to find the angles.

We have

$$\tan A = \frac{5}{4500}; \quad \therefore \log \tan A = \log 5 - \log 4500, \text{ or}$$

$\log 5 =$	0.698970
$\log 4500 =$	3.653213
difference,	$\bar{3}$.045757
adding	10
gives	7.045757
subtract $q - l$	4.685575
$\therefore x'' = 229''.1$	$\log$ 2.360182,

which is correct to 0.1 of a second. The other angle will be 89° 56′ 10″.9.

Having found 7.045757, we find the logarithm corresponding most nearly to it in the column having "Tang" at its head, and in the fourth column we find 4.685575 for the value of $q - l$, which being subtracted gives the logarithm of the seconds; the number of which is found in the table of the logarithms of numbers. For further instruction see EXPLANATION OF THE TABLES.

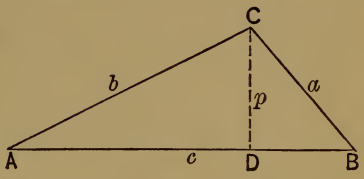
AREA OF TRIANGLES.

57. The area of a triangle equals one-half the product of the base by the altitude, or

$$K = \tfrac{1}{2}cp \tag{100}$$

where $c =$ the base, $p =$ the distance of the base from the opposite angle, and $K =$ the area.

a. Given two sides and the included angle, or b, c, A.



Here

$$p = b \sin A,$$

$$\therefore K = \tfrac{1}{2}bc \sin A. \quad (101)$$

b. Given two sides and an angle opposite one of them, or a, b, B.

$$\sin A = \frac{a}{b} \sin B; \quad (102)$$

$$\therefore A = \sin^{-1}\left(\frac{a}{b} \sin B\right). \quad (103)$$

Then

$$p'' = a \sin C = a \sin (A + B) = a \sin \left[\sin^{-1}\left(\frac{a}{b} \sin B\right) + B\right]; \quad (104)$$

$$\therefore Area = \tfrac{1}{2}ab \sin \left[\sin^{-1}\left(\frac{a}{b} \sin B\right) + B\right]. \quad (105)$$

Expanding the sine of the quantity in the brackets by equation (30) and reducing, gives

$$Area = \tfrac{1}{2}a \sin B \left[a \cos B + \sqrt{b^2 - a^2 \sin^2 B}\right]. \quad (106)$$

Interpreting this result by means of the figure, we find that if a perpendicular be dropped from C upon the side c, dividing the latter into two segments, the term $a \cos B$ in the brackets will be the length of one segment, and the other term, $\sqrt{b^2 - a^2 \sin^2 B}$, will be the length of the other segment, and hence their sum will be the length of the unknown side c, and the factor $a \sin B$ will be the length of the perpendicular from C upon the unknown side c.

If a, b, A, be given, the solution will be of the same form and the result may be found by writing A for B in equation (106) and interchanging a and b.

c. Given two angles and the included side, or A, B, c.

First find a from equation (71),

$$\frac{a}{c} = \frac{\sin A}{\sin C} = \frac{\sin A}{\sin (A + B)};$$

$$\therefore a = c \frac{\sin A}{\sin (A + B)}; \quad (107)$$

then, $$p = a \sin B$$

substituting, $$= c \frac{\sin A \sin B}{\sin (A + B)}; \tag{108}$$

$$\therefore \text{Area} = \tfrac{1}{2} c^2 \frac{\sin A \sin B}{\sin (A + B)}. \tag{109}$$

d. Given the three sides, as a, b, c.
Let $AD = x$, then $DB = c - x$,

and $$p^2 = b^2 - x^2 = a^2 - (c - x)^2; \tag{110}$$

$$\therefore x = \frac{-a^2 + b^2 + c^2}{2c}, \tag{111}$$

which substituted above gives

$$p^2 = b^2 - \left(\frac{-a^2 + b^2 + c^2}{2c}\right)^2 = \frac{4b^2 c^2 - (-a^2 + b^2 + c^2)^2}{4c^2}$$

which being the difference of two squares reduces to

$$p^2 = \frac{(2bc - a^2 + b^2 + c^2)(2bc + a^2 - b^2 - c^2)}{4c^2}$$

$$= \frac{[-a^2 + (b + c)^2][a^2 - (b - c)^2]}{4c^2}$$

$$= \frac{(a + b + c)(-a + b + c)(a - b + c)(a + b - c)}{4c^2}$$

$$= \frac{4s(s - a)(s - b)(s - c)}{c^2};$$

$$\therefore p = \frac{2}{c}\sqrt{s(s - a)(s - b)(s - c)} \tag{112}$$

where $s = \frac{1}{2}(a + b + c)$. The area will be

$$K = \sqrt{s(s - a)(s - b)(s - c)}. \tag{113}$$

Or thus; $$CD = p = b \sin A$$

Eq. (44), $$= 2b \sin \tfrac{1}{2}A \cos \tfrac{1}{2}A$$

Eqs. (86), (87), $$= \frac{2}{c}\sqrt{s(s - a)(s - b)(s - c)};$$

Eq. (100), $\therefore K = \sqrt{s(s-a)(s-b)(s-c)}$,

as before.

If p' be the perpendicular from the angle A to the side a we may write, from inspection of (112)

$$p' = \frac{2}{a}\sqrt{s(s-a)(s-b)(s-c)}; \tag{114}$$

and similar for the perpendicular from B to b,

$$p'' = \frac{2}{b}\sqrt{s(s-a)(s-b)(s-c)}; \tag{115}$$

and hence,

$$\frac{1}{p} + \frac{1}{p'} + \frac{1}{p''} = \frac{s}{K} \tag{116}$$

58. **Inscribed circle.** If a circle be inscribed in a triangle, and the centre joined with each of the angles by a right line, it will be divided into three triangles each having an altitude equal to the radius of the circle. Hence the area of the triangle will be

$$K = \tfrac{1}{2}ra + \tfrac{1}{2}rb + \tfrac{1}{2}rc = rs; \tag{117}$$

$$\therefore r = \frac{K}{s} = \frac{1}{s}\sqrt{s(s-a)(s-b)(s-c)} = \frac{pa}{2s} \tag{118}$$

59. **Circumscribed circle.** If R be the radius of the circumscribed circle, we will have

$$R = \frac{\frac{1}{2}a}{\sin A} = \frac{\frac{1}{2}b}{\sin B} = \frac{\frac{1}{2}c}{\sin C}. \tag{119}$$

60. **Escribed circles.** If r', r'', r''', be the radii of the escribed circles, opposite respectively to the sides a, b, c, then we have,

$$r' = \frac{K}{s-a}, \qquad r'' = \frac{K}{s-b}, \qquad r''' = \frac{K}{s-c} \tag{120}$$

$$\frac{1}{r} = \frac{1}{r'} + \frac{1}{r''} + \frac{1}{r'''} \tag{121}$$

$$K^2 = r \,.\, r' \,.\, r'' \,.\, r''' \tag{122}$$

(Escribed circles are exterior to the triangle, tangent to one side and to the other two prolonged.)

EXERCISES.

Find the area of the triangles, the three perpendiculars, the radii of the inscribed, circumscribed, and escribed circles, given

1. $a = 12.5$, $b = 15.2$, $c = 20.5$.

Ans. $K = 94.641+$, $R = 10.288+$, $r = 3.927+$.
$p = 15.144+$, $p' = 12.452+$, $p'' = 9.223+$.
$r' = 8.156+$, $r'' = 10.633+$. $r''' = 26.289+$.

2. $a = 16.2$, $b = 22.2$, $C = 30° 20'$.

Ans. $K = 90.814+$, $R = 11.316+$ $r = 3.632+$.
$p = 11.211+$, $p' = 8.181+$ $p''' = 15.617+$.
$r' = 10.319+$, $r'' = 32.433+$ $r''' = 6.777+$.

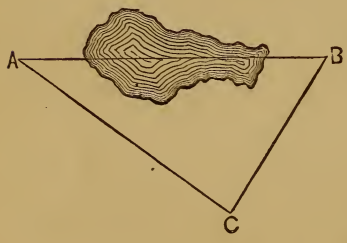
3. $a = 12.5$, $B = 40° 40'$, $C = 60° 10'$.

4. $A = 100° 10'$ $B = 50° 25'$ $c = 20.5$.

PRACTICAL EXAMPLES.

1. Find the area of a regular pentagon of which the sides are 12 feet each.

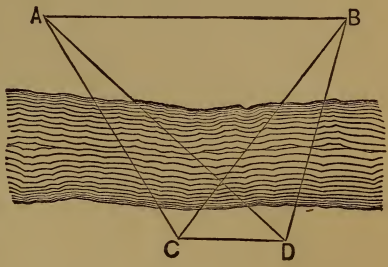
2. Find the area of a regular hexagon of which each side is 12 feet.



3. To determine the unmeasured distance AB, having given $AC = 235$ feet, $CB = 317$ feet, and the angle $ACB = 48° 45' 12''$.

4. From the top of a lighthouse 100 feet high, the angle of depression of a ship lying at anchor was $7° 43' 43''$, from the

foot of the lighthouse the angle of depression was 6° 12′ 13″; required the height of the hill on which the lighthouse was situated and the horizontal distance to the ship.



5. To determine the inaccessible distance AB, having given

$CD = 225$ feet, $ACB = 74° 15'$,
$BCD = 44° 27'$, $BDA = 66° 54'$,
and $CDA = 39° 38'$.

Ans. 528.265.

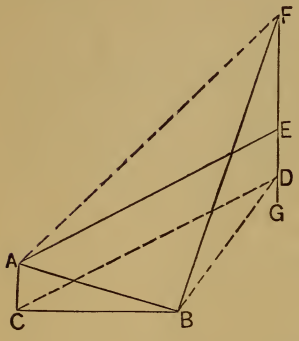
6. A headland was observed from a ship to bear directly east; after sailing S.W. 25 miles the same headland bore E. by N.; required the distance of the headland from the two points of observation.

[Instead of dividing the quadrant into 90 degrees, navigators divide it into eight equal parts called points, which are subdivided into quarters. The points as named on the card of the mariner's compass in the quadrant between north and east are as follows:

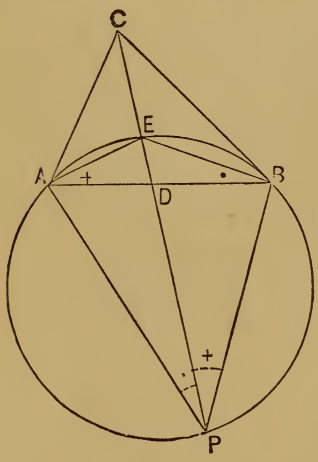
N., *N.* by *E.*, *N.N.E.*, *N.E.* by *N.*, *N.E.*, *N.E.* by *E.* *E.N.E.*, *E.* by *N.*, *E.*, and similarly for the other quadrants. Thus, *N.* by *E.* will be 11¼° *E.* of *N.*; *N.N.E.*, 22½° *E.* of *N.*, and so on.]

7. At one station a cloud bears N.N.W. and its angle of elevation is 53° 22′; at a second station, whose bearing from the first is N. by E., and distance one mile, the cloud bears west; required the height of the cloud. *Ans.* 1.427 *m.*

8. How far from the foot of a light-house can a light 350 feet high be seen out at sea, the radius of the earth being 3,956 miles? *Ans.* 22.901 *m.*



9. To determine the height of the pole FD, the base $AB = 250$ feet was measured, the end A of which was $AC = 12$ feet higher than the end B. When the transit was at B, the point D, where the horizontal line BD cut the pole was noted, the vertical angle $DBF = 12° 24'$, and the horizontal angle $DBC = 35° 15'$ were measured; and at A the horizontal angle $= DCB = 27° 51'$. Required the height FD. As a check upon the work, at A the point E may be noted, and the vertical angle EAF measured, by means of which EF may be determined, which added to ED should equal DF.



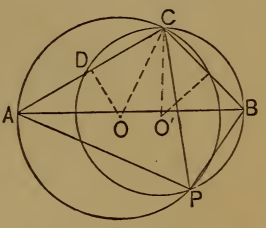
10. From a point P were measured the angles $APC = 33° 45'$, and $CPB = 22° 30'$. The distances $AC = 600$, $AB = 800$, $BC = 400$, being known, it is required to find AP and BP.

Draw a circle through the points A, B, P; join C and P, and from E, where CP intersects the circle, draw EA and EB; then will $EAB = CPB$, and $ABE = APC$, since the

former angles are subtended by the arc EB, and the latter by AE.

To find the point P by construction.

On one side of AC as a chord describe a segment of a circle which will contain an inscribed angle $= 33° 45'$, which may be done by making $ACO = 90° - 33° 45' = 56° 15'$, and intersecting CO by the perpendicular DO drawn through the middle of AC; the intersection O will be the centre of the arc, and OC the radius. Similarly, on the chord BC describe another segment of a circle that will contain an angle of $22° 30'$. The intersection P, of the two arcs will be the point sought. But four such arcs may be described, two having their centres on opposite sides of AC, and two others having their centres on opposite sides of BC; and the corresponding arcs will generally intersect in four points which may be designated by P_1, P_2, P_3, P_4. There can be no more than four points, but there may be less. In this problem there are four, as follows :



$$\begin{cases} AP_1 = 710.2 \\ BP_1 = 934\ 3 \\ CP_1 = 1042.5 \end{cases} \quad \begin{cases} AP_2 = 910.3 \\ BP_2 = 764.9 \\ CP_2 = 434.0 \end{cases} \quad \begin{cases} AP_3 = 164.3 \\ BP_3 = 960.5 \\ CP_3 = 729.6 \end{cases} \quad \begin{cases} AP_4 = 981.2 \\ BP_4 = 185.5 \\ CP_4 = 565.1 \end{cases}$$

11. From one station the angle of elevation of the top of a tower was observed to be $75° 18'$, from another station 400 feet farther from the tower the angle of elevation was $28° 45'$; required the height of the tower, the two stations being in the same horizontal plane.

SPHERICAL TRIGONOMETRY.

GEOMETRICAL PRINCIPLES.

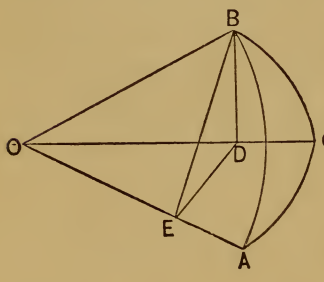
61. *A spherical triangle* is a three-sided figure on the surface of a sphere, each side being the arc of a circle. But since the sides of spherical triangles in ordinary practice are arcs of great circles, we will consider that —*A spherical triangle is formed by the arcs of three great circles.*

A great circle is one whose plane embraces the centre of the sphere. All other circles are called *small circles.*

A great circle divides the surface of the sphere into two equal parts; two great circles will generally divide the surface into four parts; and three great circles into eight parts, or eight triangles.

The sides or angles of some of these eight triangles will exceed 180°, but in this treatise only those triangles will be considered in which each part is less than 180°.

The centre O, of the sphere being common to the planes of all the great circles, the intersections of these planes necessarily radiate from that point, forming a trihedral $O-ACB$, having the three facial angles AOC, COB, AOB, and three dihedral angles, one at each of the edges of the trihedral. If with O as a centre and a common radius OA, arcs AB, AC, BC, be described, they will be on the surface of a sphere, and measure the facial angles which they subtend.



The dihedral angle between the planes AOC and AOB will be the same as the angle at A between the arcs AB and AC; for each will be measured by the angle between two lines, one in each plane, respectively perpendicular to the common intersection OA, drawn at A or at any other point of OA.

Spherical trigonometry, which is the science of the spherical triangle, may also be defined as the science of the trihedral.

It is proved in geometry, that in the spherical triangle which we are to consider :

The sum of the three angles may be anything between 180° and 540°.

The sum of the three sides is between 0° and 360°.

Each side is less than the sum of the other two.

Each side is the supplement of the angle opposite in the polar triangle.

Each angle is the supplement of the side opposite in the polar triangle.

The pole of an arc is the point where the axis of its great circle pierces the spherical surface. The arc of a great circle may be described by revolving one end of a rigid quadrant of a great circle about any point as a pole ; the remote end will trace the required arc. A string may be used in place of the rigid arc.

EXERCISES.

1. Describe the arc of a great circle on a sphere.

   [If no sphere be at hand, one may be extemporized by using an apple, ball, or some object only approximately spherical, and the solutions indicated.]

2. Describe two arcs of great circles mutually perpendicular.

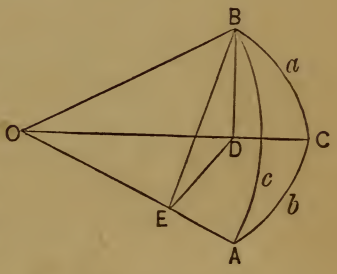
[The pole of the second arc will be at some point on the first arc.]

3. Construct three mutually perpendicular arcs of great circles.
   [They will form a tri-rectangular triangle.]
4. Construct two mutually perpendicular arcs of great circles, and cut them by a third great circle perpendicular to one and oblique to the other.
5. Construct two mutually perpendicular arcs of great circles, and cut them by a third oblique to both the former.
6. Construct a spherical triangle in which two sides are equal and each of the sides oblique to the other two.
7. Pass a great circle through three given points.
8. Given a spherical triangle; describe its polar.
9. Given a spherical triangle ; draw a perpendicular from one angle to the side opposite.
10. Describe a spherical triangle each of whose sides and angles exceeds 90°.
11. Given $a = 43° 25'$, $c = 68° 13'$, $B = 135° 47'$, to find its polar.
12. Given $A = 115° 15'$, $B = 125° 25'$, $C = 137° 37'$, to find its polar.
13. Find the polar of the triangle $A = 1° 5'$, $a = 3° 7'$, $b = 175° 2'$.
14. Find the polar of the triangle $A = 188°$, $a = 187°$, $b = 5°$.

CHAPTER IV.

OF RIGHT ANGLED SPHERICAL TRIANGLES.

62. Let ABC be a spherical triangle in which C is a right angle. The side c opposite the right angle is called the hypothenuse, the other two sides a and b, the legs of the triangle, and A and B, the oblique angles. Let O be the centre of the sphere, then will OA, OB, OC, be radii, whose lengths are each equal to unity. From B drop the perpendicular BD to the radius OC, and from D a perpendicular to the radius OA, and join B and E; then will BE also be perpendicular to OA (Geometry). Since EB and ED are respectively in the planes AOB and AOC, and perpendicular to their line of intersection, the angle between them is the angle of the dihedral, and therefore equal to A, an angle of the triangle. According to article 30, we have



$$BD = \sin a,\ OD = \cos a,\ BE = \sin c,\ OE = \cos c;$$

and according to article 5, and the values just written,

$$ED = EB \cos A = \sin c \cos A \qquad (a)$$
$$ED = BD \cot A = \sin a \cot A \qquad (b)$$
$$ED = OE \tan b = \cos c \tan b \qquad (c)$$
$$ED = OD \sin b = \cos a \sin b \qquad (d)$$

Placing equations (a) and (b) equal, and reducing by means of equation (2), we have

$$\sin a = \sin c \sin A \qquad (123)$$

similarly, $$\sin b = \sin c \sin B \qquad (124)$$

Equation (123) is written from (124) by substituting b for a and B for A. This may be done, for in the former equation a is one leg of the triangle opposite the oblique angle A; but as it is immaterial which leg and angle opposite are used, we may substitute one set for the other.

From equations (a) and (c),

$$\cos A = \tan b \cot c \qquad (125)$$

similarly, $$\cos B = \tan a \cot c \qquad (126)$$

From (a) and (d),

$$\sin c \cos A = \cos a \sin b \qquad (e)$$

From (b) and (d),

$$\sin b = \tan a \cot A \qquad (127)$$

similarly, $$\sin a = \tan b \cot B \qquad (128)$$

From (c) and (d),

$$\cos c = \cos a \cos b \qquad (129)$$

Substituting (127) in (e) gives

$$\cos A = \cos a \sin B \qquad (130)$$

similarly, $$\cos B = \cos b \sin A \qquad (131)$$

Multiplying these together and comparing with (129) gives

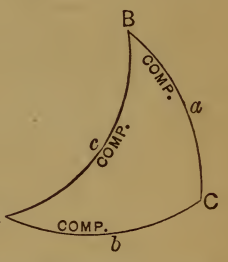
$$\cos c = \cot A \cot B. \qquad (132)$$

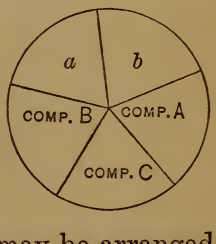
---

63. These formulas may be associated with the corresponding ones of plane triangles, and thus be more easily remembered. If the arcs be very short, we have approximately, $\sin a = a$, etc., $\tan a = a$, etc., $\cos a = 1$, nearly, etc.

In plane right triangles.		*In spherical right triangles.*	
$\sin A = \frac{a}{c}$	$\sin B = \frac{b}{c}$	$\sin A = \frac{\sin a}{\sin c}$	$\sin B = \frac{\sin b}{\sin c}$
$\cos A = \frac{b}{c}$	$\cos B = \frac{a}{c}$	$\cos A = \frac{\tan b}{\tan c}$	$\cos B = \frac{\tan a}{\tan c}$
$\tan A = \frac{a}{b}$	$\tan B = \frac{b}{a}$	$\tan A = \frac{\tan a}{\sin b}$	$\tan B = \frac{\tan b}{\sin a}$
$\sin A = \cos B$	$\sin B = \cos A$	$\sin A = \frac{\cos B}{\cos b}$	$\sin B = \frac{\cos A}{\cos a}$
$c^2 = a^2 + b^2$		$\cos c = \cos a \cos b$	
$1 = \cot A \cot B$		$\cos c = \cot A \cot B$	

64. **Napier's circular parts.** The above equations are all that are necessary for the complete solution of right triangles. Baron Napier, an eminent mathematician, made them so symmetrical that they may all be stated by two simple rules. Taking the complements of the two oblique angles, $90° - A = A'$, and $90° - B = B'$, and of the hypothenuse, $90° - c = c'$, the five quantities a, b, c', A', B', are called *Napier's circular parts.* It will be found by examining any right triangle, after neglecting the right angle that if any three parts be taken at random, one will either be between two adjacent parts or between two parts as remote as possible from it. The two former are called the *adjacent extremes*, the two latter the *opposite extremes*, and the third the *middle part.* The parts may be arranged within a circle as in the annexed figure, by means of





which the middle part and the adjacent extremes, or opposite extremes, as the case may be, may be readily selected.

EXERCISES.

1. Name Napier's *circular parts.*
2. If a, b, comp. A, be given, which will be the middle part? and will the extremes be adjacent or opposite?
3. If c' be the middle part, which will be the adjacent extremes, and which the opposite extremes?
4. If b, B, c, be given, which will be the middle part, and which the extremes? Will the extremes be adjacent or opposite?
5. If a, B, A, are the parts, which is the middle part? and which the extremes? Are they adjacent or opposite?

Napier's Rules.

65. Substituting for A, B, c, respectively $90° - A'$, $90° - B'$, $90° - c'$, and reducing, the preceding equations may be written and arranged as follows:

$$\left.\begin{array}{l} \sin\ a = \cos c' \cos A' = \tan b\ \tan B' \\ \sin\ b = \cos c' \cos B' = \tan a \tan A' \\ \sin c' = \cos a\ \cos b = \tan A' \tan B' \\ \sin A' = \cos a \cos B' = \tan b \tan c' \\ \sin B' = \cos b \cos A' = \tan a \tan c' \end{array}\right\} (C)$$

These stated as follows are *Napier's Rules:*

The sine of the middle part equals the product of the cosines *of the* opposite *extremes.*

The sine of the middle part equals the product of the tangents of the adjacent extremes.

To aid the memory in recalling these rules, it may be observed that the vowels are the same in the words *sine* and *mid*, and *cos* and *op*, also in the words *tan* and *adj.*

EXERCISES.

1. If $a = 120°$, $b = 100°$, and B is to be found, which equation of group (C) should be used, and what are the circular parts?
2. If $A = 170°$, $B = 175°$, and c is to be found, which are the circular parts and which formula should be used?
3. If $c = 90°$, find A and B, also a and b.
4. If $A = 45°$, and $B = 45°$, find c.
5. If $b = 45°$, and $A = 45°$, find B.
6. If $B = 135°$, and $b = 45°$, find a.
7. If $B = 90°$, and $a = 20°$, find A and b.
8. If the five parts are—the oblique angles, the hypothenuse, and the complements of the sides; deduce two rules similar to Napier's.

   [They are called Maudit's Rules.]

---

66. *The species of the parts* are their relations to 90°. If two parts are both less than 90° they are of the same species; also if both are between 90° and 180°. But if one is between 0° and 90°, and the other between 90° and 180°, they are of different species. When the result is found in terms of the sine of the angle, it will be ambiguous unless the particular angle can be determined by its relation to the given parts.

In a right angled spherical triangle, if the hypothenuse is less than 90°, *the two sides and the two oblique angles are, respectively, of the same species.*

For, from the third of group (C) we will have $c' < 90°$, and sin c' *positive;* hence

$$\cos a \cos b$$

must be positive, and therefore cos a and cos b must have the same sign; hence if a is less than 90° b must also be less. Similarly, from the same equation,

$$\tan A' \tan B', \text{ or } \cot A \cot B,$$

must be positive and A and B must both be less or both greater than 90°.

In a right spherical triangle, if the hypothenuse exceeds 90° *the two sides and the two oblique angles will, respectively, be of different species.*

For, in the third of group (C), $\sin c' = \cos c$ will be negative, hence $\cos a$ and $\cos b$ will have opposite signs; and similarly in regard to A and B.

In a right spherical triangle, an angle and its opposite side are of the same species.

For, by the fifth of group (C), we have

$$\sin A = \frac{\cos B}{\cos b}, \tag{133}$$

and since $\sin A$ will be positive ($A < 180°$), $\cos B$ and $\cos b$ must have the same sign, and hence the angles will be both less or both greater than 90°.

The solution of right spherical triangles may be classed under six cases, as follows:

67. **Case I.** *Given the hypothenuse and a side,* as c and a.

To find A. Here a is the middle part, and from the first of group (C) we have

$$\sin A = \frac{\sin a}{\sin c}$$

or, $$\log \sin A = \log \sin a - \log \sin c \tag{134}$$

To find B. In this case B is the middle part and the fifth of group (C) gives

$$\cos B = \tan a \cot c$$

or, $$\log \cos B = \log \tan a + \log \cot c \tag{135}$$

To find b. Here c is the middle part, and the third of (C) gives

$$\cos b = \frac{\cos c}{\cos a}$$

or,
$$\log \cos b = \log \cos c - \log \cos a \qquad (136)$$

Check. The third of (C) gives

$$\cos B = \cos b \sin A$$

or,
$$\log \cos B = \log \cos b + \log \sin A \qquad (137)$$

EXAMPLES.

1. Given $a = 20°$ $c = 140°$.

	By (134)	By (135)	By (136)
	log	log	log
$a = 20°$	sin 9.534052	tan 9.561066	ar co cos 0.027014
$c = 140°$	ar co sin 0.191932	cot 10.076187n	cos 9.884254n
	A, sin 9.725984	B, cos 9.637253n	b, cos 9.911268n
		Check, By (137), A, sin	9.725984
		B, cos	9.637252n

which being the same as before found checks the work. Taking the angles from a table of logarithmic functions gives

Ans. $A = 32° 8' 48''$, $B = 115° 42' 23''$, $b = 144° 36' 28''$.

[n implies that the function is negative; thus cot 140° is negative. Since the sign of the result depends upon the number of negative factors, if there be but one n the result will be negative, and, similarly, if there be an odd number of n's in the logarithms added, the result will be negative; but if there be an even number of n's the sign of the result will be positive.

The last figure or figures of the logarithm of the "check" may not agree exactly with that previously found, and yet the work may be correct, for the last figure of a logarithm in the table is not always correct.]

2. Given $a = 141° 11'$, $c = 127° 12'$.
Ans. $A = 128° 5' 54''$, $B = 52° 21' 45''$, $b = 39° 6' 23''$.

3. Given $b = 18° 01' 50''$, $c = 86° 51'$.
Ans. $A = 88° 58' 25'$, $B = 18° 03' 32''$, $a = 86° 41' 14''$.

---

68. **Case II.** *Given one angle and its opposite side,* as A and a.

To find c. By Napier's Rules,

$$\sin c = \frac{\sin a}{\sin A} \tag{138}$$

To find b,

$$\sin b = \tan a \cot A \tag{139}$$

To find B,

$$\sin B = \frac{\cos A}{\cos a} \tag{140}$$

Check,

$$\sin b = \sin c \sin B \tag{141}$$

In this case the ambiguity is not removed by the tests in article 66, and hence there will, generally, be two solutions.

EXAMPLES.

1. Given $B = 150°$, $b = 160°$.

Ans. $\left.\begin{aligned} c &= 136° 50' 23'' \\ a &= 39° 4' 50'' \\ A &= 67° 9' 42'' \end{aligned}\right\}$ or $\left\{\begin{aligned} c &= 43° 9' 36'' \\ a &= 140° 55' 9'' \\ A &= 112° 50' 17'' \end{aligned}\right.$

According to article 66, a and A must be in the same quadrant.

2. Given $A = 37° 28'$, $a = 35° 44'$.

Ans. $c = 73° 45' 15''$, $B = 77° 54'$, $b = 69° 50' 24''$ or $c = 106° 14' 45''$, $B = 102° 6'$, $b = 110° 9' 36''$

3. Given $A = 104° 59'$ $a = 129° 33'$.

Ans. $c = 127° 2' 27''$, $B = 23° 57' 19''$, $b = 18° 54' 38''$ or $c = 52° 57' 33''$, $B = 156° 2' 41''$, $b = 161° 5' 22''$

4. Given $B = 80° 1'$, $b = 67° 36'$.

5. Given $B = 45°$, $b = 45°$.

---

69. **Case III.** *Given the hypothenuse and one angle.*

[The student may select the formulas for this and the remaining cases from group (C).]

EXAMPLES.

1. Given $A = 23° 28'$, $c = 145°$.

Ans. $B = 109° 34' 33''$, $a = 13° 12' 12''$, $b = 147° 17' 15''$.

2. Given $B = 50° 8' 21''$, $c = 32° 34'$.

Ans. $A = 44° 44'$, $a = 22° 15' 43''$, $b = 24° 24' 19''$.

3. Given $B = 80° 55' 27''$, $c = 98° 6' 43''$.

Ans. $A = 131° 27' 18''$, $a = 132° 6'$, $b = 77° 51'$.

---

70. **Case IV.** *Given an angle and a side adjacent.*

EXAMPLES.

1. Given $a = 118° 54'$, $B = 12° 19'$.

Ans. $c = 118° 20' 20''$, $A = 95° 55' 2''$, $b = 10° 49' 17''$.

2. Given $b = 54° 30'$, $A = 35° 30'$.
Ans. $c = 59° 51' 20''.8$, $a = 30° 8' 39''.2$, $B = 70° 17' 35''$.

3. Given $B = 137° 24' 21''$, $a = 29° 46' 08''$.
Ans. $b = 155° 27' 54''$, $c = 142° 9' 13''$, $A = 54° 1' 16''$.

---

71. Case V. *Given the two sides,* a and b.

EXAMPLES.

1. Given $a = 56° 34'$, $b = 27° 18'$.
Ans. $A = 16° 50' 47''$, $B = 31° 44' 9''$, $c = 60° 41' 9''$.

2. Given $a = 144° 27' 03''$, $b = 32° 8' 56''$.
Ans. $A = 126° 40' 24''$, $B = 47° 13' 43''$, $c = 133° 32' 26''$

3. Given $a = 32° 9' 17''$, $b = 32° 41'$.
Ans. $A = 49° 20' 17''$, $B = 50° 19' 16''$, $c = 44° 33' 17''$.

---

72. Case VI. *Given the two oblique angles,* A and B.

EXAMPLES.

1. Given $A = 91° 11'$, $B = 111° 11'$.
Ans. $c = 89° 32' 29''$, $a = 91° 16' 8''$, $b = 111° 11' 16''$

2. Given $A = 67° 54' 47''$, $B = 99° 57' 35''$.
Ans. $a = 67° 33' 27''$, $b = 100° 45'$, $c = 94° 5'$.

3. Given $A = 54° 01' 15''$, $B = 137° 24' 21''$.
Ans. $a = 29° 46' 08''$, $b = 155° 27' 55''$, $c = 142° 09' 12''$.

---

73. *A quadrantal triangle* is one having one or more of its sides equal to a quadrant. Its polar triangle will be right angled; hence to solve a quadrantal triangle pass to its polar, solve that, and pass back to the original triangle.

EXAMPLES.

1. Given $c = 90°$, $B = 74° 45'$, $a = 18° 12'$, to find the remaining parts.
   Ans. $C = 104° 31' 13''$, $b = 4° 42' 15''$, $A = 71° 10' 54''$.

2. Given $c = 90°$, $A = 42° 01'$, $B = 121° 20'$ to find the remaining parts.
   Ans. $C = 66° 57' 15''$, $b = 111° 50' 18''$, $a = 45° 40' 17''$.

---

74. If the angle sought be near zero, or ninety degrees, it may sometimes be found more accurately with ordinary logarithmic tables by means of special formulæ, a few of which are here given without proof.

$$\tan^2 (45° - \tfrac{1}{2}A) = \tan \tfrac{1}{2}(c - a) \cot \tfrac{1}{2}(c + a)$$
$$\tan^2 \tfrac{1}{2}b = \tan \tfrac{1}{2}(c - a) \tan \tfrac{1}{2}(c + a)$$
$$\tan^2 \tfrac{1}{2}B = \sin (c - a) \csc \tfrac{1}{2}(c + a) \qquad [56, 131, 30 \div 31]$$
$$\tan^2 \tfrac{1}{2}c = -\cos (A + B) \sec (A - B) \qquad [56, 129, 32 \div 33]$$
$$\tan^2 (45° - \tfrac{1}{2}c) = \tan \tfrac{1}{2}(A - a) \cot \tfrac{1}{2}(A + a)$$

To obtain the first of these, we have from equation (123)

$$\sin A = \frac{\sin a}{\sin c};$$

$$\therefore \frac{1 - \sin A}{1 + \sin A} = \frac{\sin c - \sin a}{\sin c + \sin a} = \tan \tfrac{1}{2}(c - a) \cot \tfrac{1}{2}(c + a).$$

In equation (66) make $x = 90°$, and it will readily be found that the left member of the above equation reduces to $\tan^2 (45° - \frac{1}{2}A)$.

The fifth equation above may be found in a similar manner by beginning with equation (123) after writing it thus :

$$\sin c = \frac{\sin a}{\sin A}.$$

To obtain the second equation above:

[Eq. (56)] $$\tan^2 \tfrac{1}{2}b = \frac{1 - 2 \cos b + \cos^2 b}{1 - \cos^2 b},$$

[Eq. (129)] $$\cos^2 \tfrac{1}{2}b = \cos^2 c \div \cos^2 a,$$

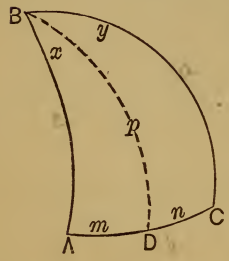
which substituted in the preceding and reduced by the aid of (67) multiplied by (69) will at once give the required result.

CHAPTER V.

OBLIQUE ANGLED TRIANGLES SOLVED BY MEANS OF RIGHT ANGLED TRIANGLES.

75. *In a spherical triangle the sines of the angles are proportional to the sines of the sides opposite.*

In the spherical triangle ABC, let fall the perpendicular BD from any angle B upon the opposite side, AC, thus forming two right angled triangles ADB and CDB; of which let m be the base of one, and n that of the other, x the angle opposite m and y that opposite n, as in the figure. According to Napier's rules, we have for the



triangle ADB, $$\sin p = \sin c \sin A \qquad (142)$$

triangle CDB, $$\sin p = \sin a \sin C \qquad (143)$$

Therefore,

$$\left.\begin{aligned} &\sin a \sin C = \sin c \sin A \\ \text{similarly,}\quad &\sin b \sin A = \sin a \sin B \\ &\sin c \sin B = \sin b \sin C \end{aligned}\right\} \qquad (144)$$

These may be written

$$\frac{\sin a}{\sin A} = \frac{\sin b}{\sin B} = \frac{\sin c}{\sin C} \qquad (145)$$

which was to be proved.

76. *To find the segments m and n, given the three sides.*
From Napier's first rule,

$$\cos a = \cos p \cos n$$
$$\cos c = \cos p \cos m$$

Divide the former by the latter; then after adding each term to unity, and subtracting each term from unity, divide the latter by the former, and find

$$\frac{\cos c - \cos a}{\cos c + \cos a} = \frac{\cos m - \cos n}{\cos m + \cos n}$$

But, (69),

$$\frac{\cos c - \cos a}{\cos c + \cos a} = \tan \tfrac{1}{2}(a + c) \tan \tfrac{1}{2}(a - c)$$

and

$$\frac{\cos m - \cos n}{\cos m + \cos n} = \tan \tfrac{1}{2}(n + m) \tan \tfrac{1}{2}(n - m)$$

$$\therefore \tan \tfrac{1}{2}(a + c) \tan \tfrac{1}{2}(a - c) = \tan \tfrac{1}{2}b \tan \tfrac{1}{2}(n - m) \quad (146)$$

from which $n - m$ may be found; and since $n + m = b$, the values of n and m become known.

By means of Napier's rules and equation (146) all the cases of oblique triangles may be solved, and the solution may sometimes be facilitated by means of equations (144).

The perpendicular BD may fall entirely without the triangle, and if it falls to the right of BC, n will be entirely on the prolongation of the base, and m will be the entire base *plus* the elongation. This perpendicular will also meet the great circle of the base in two points, distant from each other 180°, and if that perpendicular be taken whose foot is nearest to one end or the other of the base, then will $m + n$ be numerically less than 180°, as it should. If n be the external segment, it will be considered as *minus*, so that, algebraically, we will have in all cases $m + n = b$, which, numerically, may sometimes be $m - n = b$.

Since the greater segment is not necessarily adjacent to the greater

side, its position must be determined. This may be done by means of equation (146); for the signs of all the factors except the last will be determined from the data, and therefore the sign of $\tan \frac{1}{2}(n - m)$ becomes known, and since $\frac{1}{2}(n - m)$ will be numerically less than 90°, it follows that when $\tan \frac{1}{2}(n - m)$ is +, $n > m$, and if it be −, $n < m$.

In the solution of oblique spherical triangles, we may have six cases, as follows:

77. **Case I.** *Given two sides and the included angle,* as a, b, C.

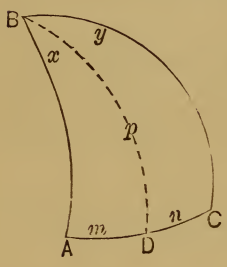
From the angle B drop the perpendicular p on the side opposite; then find p by means of equation (143).

Find the segment n by means of the second of Napier's rules (observing the species), which will give

$$\tan n = \frac{\cos C}{\tan a}; \tag{147}$$

then

$$m = b - n \tag{148}$$



Knowing m and p, find A by Napier's first rule, and c by the second, giving

$$\cot A = \frac{\sin m}{\tan p}, \tag{149}$$

$$\cos c = \cos p \cos m \tag{150}$$

Find B by means of $(144)_2$; or find x and y by means of the right triangles, in which case $B = x + y$.

---

78. **Case II.** *Given two angles and the included side.* Pass to the polar and solve by Case I., then pass

back. Or, given C, B, a, by means of Napier's rules, find n, p, y; then $x = B - y$, and with x and p complete the solution.

---

79. **Case III.** *Given two sides and an angle opposite one of them*, as a, c, A.

Find the angle C by means of $(144)_1$. Then by Napier's rules

$$\cos A = \tan c \tan m \qquad (151)$$

$$\cos C = \tan a \cot n \qquad (152)$$

by means of which m and n may be found, then

$$b = m + n,$$

after which B may be found by means of equation $(144)_2$.

This case admits of two solutions, one or none, which may be shown in the same manner as in article 52, Case II., of plane triangles.

If $a > p$, and $a < c$, there will be two triangles.

If $a = p$, there will be one triangle.

If $a < p$, there will be no triangle.

If $a = c$, there will be one triangle.

If $a > c$, and $A < 90°$ or $A > 90°$, there will be one triangle.

If $a > c$ and $A = 90°$, there will be two triangles.

---

80. **Case IV.** *Given two angles and a side opposite one of them*, as A, C, a.

Pass to the polar, solve that by Case III., and then pass back. Or, solve directly, finding c by $(144)_1$, m and n by (151) and (152); then $b = m + n$, after which B may be found by $(144)_2$.

81. **Case V.** *Given the three sides.*

By means of (148) we have

$$\tan \tfrac{1}{2}(n-m) = \tan \tfrac{1}{2}(a+c) \tan \tfrac{1}{2}(a-c) \cot \tfrac{1}{2}(n+m), \quad (153)$$

from which find n and m; after which the solution may be computed by Napier's rules.

---

82. **Case VI.** *Given the three angles.*

Pass to the polar, solve that by Case V., and then pass back.

EXAMPLES.

1. Given $A = 92°\ 10'$, $B = 72°\ 15'$, and $C = 135°\ 15'\ 20''$, to solve the triangle.

This comes under case VI., and we have, passing to the polar,

$$a' = 87°\ 50',\ b' = 107°\ 45',\ c' = 44°\ 47'\ 40''.$$

		By (153)
$\frac{1}{2}(a'+c') =$	$66°\ 17'\ 20''$	log tan 10.357337
$\frac{1}{2}(a'-c') =$	$21°\ 32'\ 40''$	log tan 9.596384
$\frac{1}{2}(n+m) =$	$53°\ 52'\ 30''$	log cot 9.863252
$\frac{1}{2}(n-m) =$	$33°\ 16'\ 9''$	log tan 9.816973

		By (125)	By (125)
$\therefore n =$	$87°\ 08'\ 39''$	log tan 11.302022	
$m =$	$20°\ 36'\ 21''$		log tan 9.575178
$a' =$	$87°\ 50'\ 00''$	log cot 8.577877	
$c' =$	$44°\ 44'\ 40''$		log cot 10.003875
$C' =$	$40°\ 40'\ 35''$	log cos 9.879899	
$A' =$	$67°\ 42'\ 21''$		log cos 9.579053

To find B'.

		By (132)	By (132)
$a' =$	$87° 50' 00''$	log sec 11.422434	
$C' =$	$40° 40' 35''$	log cot 10.065795	
$c' =$	$44° 44' 40''$		log sec 10.148587
$A' =$	$67° 42' 2''$		log cot 9.612795
$y =$	$88° 08' 21''$	log tan 11.488229	
$x =$	$29° 59' 48''$		log tan 9.761382
$C' =$	$118° 08' 09''$		

Passing back we find

Ans. $\begin{cases} a = 112° 17' 39'' \\ b = 139° 19' 25'' \\ c = 61° 51' 51'' \end{cases}$

2. Given $a = 62°$, $b = 75°$, $C = 100°$.
3. Given $A = 150°$, $b = 60°$ $C = 120°$.
4. Given $A = 50° 12'$, $B = 58° 08'$, $a = 62° 42'$, to find the other parts.

Ans. $\begin{cases} b = 79° 12' 10'', & c = 119° 03' 26'', & C = 130° 54' 28'' \\ \text{or } b = 100° 47' 50'', & c = 152° 14' 18'', & C = 156° 15' 6'' \end{cases}$

5. Given $a = 90°$, $b = 90°$, $c = 90°$.
6. Given $a = 45°$, $b = 45°$, $c = 45°$.
7. Given $a = 175°$, $b = 175°$, $c = 5°$.
8. Given $a = 84° 14' 29''$, $b = 44° 13' 45''$, and $A = 130° 5' 22''$ to find the other parts.

Ans. $B = 32° 26' 6\frac{2}{3}''$, $C = 36° 45' 28''$, $c = 51° 6' 12''$.

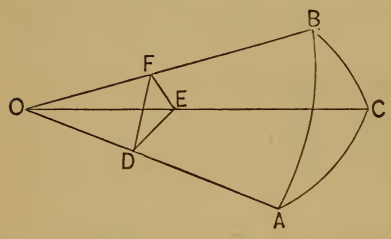
9. Given the two sides $44° 13' 45''$ and $84° 14' 29''$, and the included angle $36° 45' 28''$; to find the other parts.

Ans. Angles $32° 26' 6''$, and $130° 5' 22''$, side $51° 6' 12''$.

CHAPTER VI.

GENERAL FORMULÆ.

83. *Value of the cosine of a side of a spherical triangle.* Let ABC be a spherical triangle, O the centre of the sphere, $O - ABC$ the trihedral. Conceive the trihedral to be cut by a plane perpendicular to the edge OA, passing through any point D, and let DF, DE, EF, be the intersections with its faces. Then will DF and DE be perpendicular to OA, the triangles ODF and ODE will be right, and the angle $EDF = A$.



We have, article 55,

$$EF^2 = OE^2 + OF^2 - 2OE \,.\, OF \cos a \qquad (a)$$

$$EF^2 = DE^2 + DF^2 - 2DE \,.\, DF \cos A \qquad (b)$$

$$OD^2 = OE^2 - DE^2 \qquad (c)$$

$$OD^2 = OF^2 - DF^2 \qquad (d)$$

Subtracting (b) from (a) and reducing by (c) and (d), gives

$$\cos a = \frac{OD}{OE} \cdot \frac{OD}{OF} + \frac{DE}{OE} \cdot \frac{DF}{OF} \cos A.$$

Substituting the trigonometrical functions, group (A),

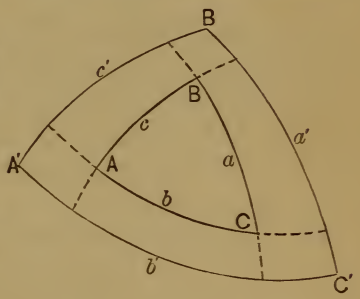
$$\left.\begin{aligned} \cos a &= \cos b \cos c + \sin b \sin c \cos A \\ \cos b &= \cos c \cos a + \sin c \sin a \cos B \\ \cos c &= \cos a \cos b + \sin a \sin b \cos C \end{aligned}\right\} \quad (154)$$

To aid in memorizing these, observe that the first and last are *cos* of letter of same name, thus cos a and cos A, the former small the latter large; also that cos A is joined to the factors of sines of the other sides.

Also observe that the second equation may be written from the first by advancing the letters one in the scale a, b, c, a; thus, for a write b, for b, c, and for c write a. Similarly the third may be found from the second.

84. Let $A'B'C'$ be a spherical triangle polar to ABC, then by geometry,

$$A' = 180° - a \qquad a' = 180° - A$$
$$B' = 180° - b \qquad b' = 180° - B$$
$$C' = 180° - c \qquad c' = 180° - C$$



The first of (154) applied to the triangle $A'B'C'$, gives

$$\cos a' = \cos b' \cos c' + \sin b' \sin c' \cos A',$$

in which substituting the above values, we have

$$-\cos A = (-\cos B)(-\cos C) + \sin B \sin C (-\cos a)$$

or

$$\left.\begin{aligned} \cos A &= -\cos B \cos C + \sin B \sin C \cos a \\ \cos B &= -\cos C \cos A + \sin C \sin A \cos b \\ \cos C &= -\cos A \cos B + \sin A \sin B \cos c \end{aligned}\right\} \quad (155)$$

Thus, by the use of the polar triangle, formulæ may be obtained in which the functions of the angles and sides may be found in place of the sides and angles.

---

85. Substituting $\cos a$ from $(155)_1$, in $(154)_2$, we have

$$\cos b = \cos^2 c \cos b + \sin b \cos c \sin c \cos A + \sin a \sin c \cos B$$

But,

$$\cos^2 c \cos b = (1 - \sin^2 c) \cos b = \cos b - \cos b \sin^2 c$$

which substituted and dividing by $\sin c$, gives

$$\left.\begin{aligned} \sin a \cos B &= \sin c \cos b - \sin b \cos c \cos A \\ \sin b \cos C &= \sin a \cos c - \sin c \cos a \cos B \\ \sin c \cos A &= \sin b \cos a - \sin a \cos b \cos C \end{aligned}\right\} \quad (156)$$

---

86. From $(144)_2$ we have

$$\frac{\sin a \sin B}{\sin A} = \sin b$$

which, divided into $(156)_1$ member by member, we have

$$\left.\begin{aligned} \sin A \cot B &= \sin c \cot b - \cos c \cos A \\ \text{and,} \quad \sin B \cot C &= \sin a \cot c - \cos a \cos B \\ \sin C \cot A &= \sin b \cot a - \cos b \cos C \end{aligned}\right\} \quad (157)$$

In the triangle ABC, A and B may be interchanged provided that a and b are also interchanged. Interchanging these letters in the precedi g equations, gives,

$$\left.\begin{aligned} \sin B \cot A &= \sin c \cot a - \cos c \cos B \\ \sin A \cot C &= \sin b \cot c - \cos b \cos A \\ \sin C \cot B &= \sin a \cot b - \cos a \cos C \end{aligned}\right\} \quad (158)$$

In these equations the permutations may be made by passing backward with the letters, thus, C, B, A, C, or by beginning with the third equation and writing the 2d from it by permuting the letters in their natural order, and the first from the second in the same manner.

---

87. To transform (154) and (155) so as to adapt them to logarithmic computation.

In (154) substitute

Eq. (46), $\cos A = 1 - 2 \sin^2 \frac{1}{2}A$

then

$$\cos a = \cos (b - c) - 2 \sin b \cos c \sin^2 \tfrac{1}{2}A$$

$$\therefore 2 \sin^2 \tfrac{1}{2}A = \frac{\cos (b - c) - \cos a}{\sin b \sin c} \quad (159)$$

If $x = a$, and $y = b - c$

then

$\frac{1}{2}(x + y) = \frac{1}{2}(a + b - c)$, $\frac{1}{2}(x - y) = \frac{1}{2}(a - b + c)$

and (Eq. (65)),

$\cos (b - c) - \cos a = 2 \sin^2 \frac{1}{2}(a - b + c) \sin \frac{1}{2}(a - b + c)$,

which substituted in (159) gives

$$\sin^2 \tfrac{1}{2}A = \frac{\sin \frac{1}{2}(a - b + c) \sin \frac{1}{2}(a + b - c)}{\sin b \sin c} \quad (160)$$

Let s be one half the sum of the sides, that is,

$$a + b + c = 2s$$

then $a - b + c = a + b - 2b + c = 2(s - b)$

$a + b - c = a + b + c - 2c = 2(s - c)$

which substituted in (160) gives

$$\left.\begin{aligned} \sin^2 \tfrac{1}{2}A &= \frac{\sin(s-b)\ \sin(s-c)}{\sin b \sin c} \\ \text{similarly,}\quad \sin^2 \tfrac{1}{2}B &= \frac{\sin(s-c)\ \sin(s-a)}{\sin c \sin a} \\ \sin^2 \tfrac{1}{2}C &= \frac{\sin(s-a)\ \sin(s-b)}{\sin a \sin b} \end{aligned}\right\} \quad (161)$$

Passing to the polar triangle,

$$\left.\begin{aligned} \cos^2 \tfrac{1}{2}a &= \frac{\sin(S-B)\ \sin(S-C)}{\sin B \sin C} \\ \cos^2 \tfrac{1}{2}b &= \frac{\sin(S-C)\ \sin S-A)}{\sin C \sin A} \\ \cos^2 \tfrac{1}{2}c &= \frac{\sin(S-A)\ \sin(S-B)}{\sin A \sin B} \end{aligned}\right\} \quad (162)$$

Again, substituting,

Eq. (47), $\cos A = 2\cos^2 \tfrac{1}{2}A - 1$

in $(154)_1$ gives

$$\cos a = \cos(b + c) + 2 \sin b \sin c \cos^2 \tfrac{1}{2}A\ ;$$

$$\therefore\ \cos^2 \tfrac{1}{2}A = \frac{\cos a - \cos(b + c)}{2 \sin b \sin c}$$

$$\left.\begin{aligned} \text{or}\quad \cos^2 \tfrac{1}{2}A &= \frac{\sin s \sin(s-a)}{\sin b \sin c} \\ \text{similarly,}\quad \cos^2 \tfrac{1}{2}B &= \frac{\sin s \sin(s-b)}{\sin c \sin a} \\ \cos^2 \tfrac{1}{2}C &= \frac{\sin s \sin(s-c)}{\sin a \sin b} \end{aligned}\right\} \quad (163)$$

Passing to the polar triangle,

$$\left.\begin{aligned} \sin^2 \tfrac{1}{2}a &= \frac{-\cos S \cos (S-A)}{\sin B \sin C} \\ \sin^2 \tfrac{1}{2}b &= \frac{-\cos S \cos (S-B)}{\cos C \cos A} \\ \sin^2 \tfrac{1}{2}c &= \frac{-\cos S \cos (S-C)}{\cos A \cos B} \end{aligned}\right\} \quad (164)$$

---

88. From (161) and (163) we find, observing that $\sin \frac{1}{2}A \div \cos \frac{1}{2}A = \tan \frac{1}{2}A$,

$$\left.\begin{aligned} \tan^2 \tfrac{1}{2}A &= \frac{\sin (s-b) \sin (s-c)}{\sin s \sin (s-a)} \\ \tan^2 \tfrac{1}{2}B &= \frac{\sin (s-c) \sin (s-a)}{\sin s \sin (s-b)} \\ \tan^2 \tfrac{1}{2}C &= \frac{\sin (s-a) \sin (s-b)}{\sin s \sin (s-c)} \end{aligned}\right\} \quad (165)$$

Passing to the polar triangle; or by means of (164) and (162) we have

$$\left.\begin{aligned} \tan^2 \tfrac{1}{2}a &= \frac{-\cos S \cos (S-A)}{\cos (S-B) \cos (S-C)} \\ \tan^2 \tfrac{1}{2}b &= \frac{-\cos S \cos (S-B)}{\cos (S-C) \cos (S-A)} \\ \tan^2 \tfrac{1}{2}c &= \frac{-\cos S \cos (S-C)}{\cos (S-A) \cos (S-B)} \end{aligned}\right\} \quad (166)$$

---

89. Where several parts—as for instance all the angles—are to be found, it may be better to proceed as follows:

Let

$$k = \sqrt{\frac{\sin(s-a)\sin(s-b)\sin(s-c)}{\sin s}} \tag{167}$$

then (165) become

$$\left.\begin{aligned} \tan \tfrac{1}{2}A &= \frac{k}{\sin(s-a)} \\ \tan \tfrac{1}{2}B &= \frac{k}{\sin(s-b)} \\ \tan \tfrac{1}{2}C &= \frac{k}{\sin(s-c)} \end{aligned}\right\} \tag{168}$$

Similarly, put

$$K = \sqrt{\frac{-\cos S}{\cos(S-A)\cos(S-B)\cos(S-C)}} \tag{169}$$

then (166) become

$$\left.\begin{aligned} \tan \tfrac{1}{2}a &= K\cos(S-A) \\ \tan \tfrac{1}{2}b &= K\cos(S-B) \\ \tan \tfrac{1}{2}c &= K\cos(S-C) \end{aligned}\right\} \tag{170}$$

---

90. **To deduce Napier's Analogies,** which are

$$\left.\begin{aligned} \frac{\tan \frac{1}{2}c}{\tan \frac{1}{2}(a-b)} &= \frac{\sin \frac{1}{2}(A+B)}{\sin \frac{1}{2}(A-B)} \\ \frac{\cot \frac{1}{2}C}{\tan \frac{1}{2}(A-B)} &= \frac{\sin \frac{1}{2}(a+b)}{\sin \frac{1}{2}(a-b)} \\ \frac{\tan \frac{1}{2}c}{\tan \frac{1}{2}(a+b)} &= \frac{\cos \frac{1}{2}(A+B)}{\cos \frac{1}{2}(A-B)} \\ \frac{\cot \frac{1}{2}C}{\tan \frac{1}{2}(A+B)} &= \frac{\cos \frac{1}{2}(a+b)}{\cos \frac{1}{2}(a-b)} \end{aligned}\right\} \tag{171}$$

Dividing $(165)_1$ by $(165)_2$ gives

$$\frac{\tan \frac{1}{2}A}{\tan \frac{1}{2}B} = \frac{\sin (s-b)}{\sin (s-a)}$$

By composition and division, we have

$$\frac{\tan \frac{1}{2}A + \tan \frac{1}{2}B}{\tan \frac{1}{2}A - \tan \frac{1}{2}B} = \frac{\sin (s-b) + \sin (s-a)}{\sin (s-b) - \sin (s-a)}$$

Equation (66),

$$= \frac{\tan \frac{1}{2}(s-b+s-a)}{\tan \frac{1}{2}(s-b-(s-a))}$$

$$= \frac{\tan \frac{1}{2}c}{\tan \frac{1}{2}(a-b)}$$

To reduce the left member, we have from (30) and (31)

$$\frac{\sin (x+y)}{\sin (x-y)} = \frac{\sin x \cos y + \cos x \sin y}{\sin x \cos y - \cos x \sin y},$$

and dividing both numerator and denominator of the right member by $\cos x \cos y$ we find

$$\frac{\sin (x+y)}{\sin (x-y)} = \frac{\tan x + \tan y}{\tan x - \tan y}$$

Making $x = \frac{1}{2}A$, and $y = \frac{1}{2}B$, we have

$$\frac{\tan \frac{1}{2}A + \tan \frac{1}{2}B}{\tan \frac{1}{2}A - \tan \frac{1}{2}B} = \frac{\sin \frac{1}{2}(A+B)}{\sin \frac{1}{2}(A-B)} = \frac{\tan \frac{1}{2}c}{\tan \frac{1}{2}(a-b)}$$

which is $(171)_1$.

Passing to the polar triangle we have

$$\frac{\sin \frac{1}{2}(a+b)}{\sin \frac{1}{2}(a-b)} = \frac{\cot \frac{1}{2}C}{\tan \frac{1}{2}(A-B)}$$

which is $(171)_2$.

Multiplying $(165)_1$ by $(165)_2$,

$$\tan \tfrac{1}{2}A \tan \tfrac{1}{2}B = \frac{\sin (s-c)}{\sin s}$$

or,

$$1 : \tan \tfrac{1}{2}A \tan \tfrac{1}{2}B :: \sin s : \sin (s-c),$$

which by composition and division,

$$\frac{1 - \tan \frac{1}{2}A \tan \frac{1}{2}B}{1 + \tan \frac{1}{2}A \tan \frac{1}{2}B} = \frac{\sin s - \sin (s-c)}{\sin s + \sin (s-c)}$$

Equation (66), $$= \frac{\tan \frac{1}{2}c}{\tan \frac{1}{2}(a+b)}$$

hence $$\frac{\cos \frac{1}{2}(A+B)}{\cos \frac{1}{2}(A-B)} = \frac{\tan \frac{1}{2}c}{\tan \frac{1}{2}(a+b)}$$

which is $(171)_3$.

Passing to the polar gives

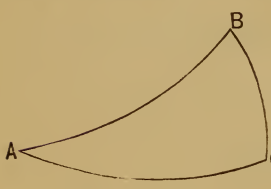
$$\frac{\cos \frac{1}{2}(a+b)}{\cos \frac{1}{2}(a-b)} = \frac{\cot C}{\tan \frac{1}{2}(A+B)}$$

which is $(171)_4$.

These equations are especially useful in solving a triangle in which two sides and the included angle, or two angles and included side, are given. In using them the species of the parts must be observed. In the first, $\tan \frac{1}{2}(a-b)$ and $\sin \frac{1}{2}(A-B)$ are necessarily of the same species, and therefore $\tan \frac{1}{2}c$ and $\sin \frac{1}{2}(A+B)$ must be of the same species. Similarly, in the second, $\tan \frac{1}{2}(A-B)$ and $\sin \frac{1}{2}(a-b)$ are of the same species, and therefore $\cot \frac{1}{2}C$ and $\sin \frac{1}{2}(a+b)$ must be of the same species.

By means of the general equations the solutions of the six cases may be made as follows:

91. Case I. *Given two sides and the included angle,* as a, b, C, to find the remaining parts.



To find the angles A and B.

From $(171)_2$ and $(171)_4$ we have

$$\tan \tfrac{1}{2}(A-B) = \frac{\sin \frac{1}{2}(a-b)}{\sin \frac{1}{2}(a+b)} \cot \tfrac{1}{2}C \qquad (173)$$

$$\tan \tfrac{1}{2}(A+B) = \frac{\cos \frac{1}{2}(a-b)}{\cos \frac{1}{2}(a+b)} \cot \tfrac{1}{2}C \qquad (174)$$

by means of which $\frac{1}{2}(A - B)$ and $\frac{1}{2}(A + B)$ may be found, and of the last two expressions the sum is A, and the difference B.

To find c. From $(144)_1$ we have

$$\sin c = \frac{\sin C}{\sin A} \sin a \qquad (175)$$

EXAMPLE.

Given $a = 73° 58'$, $b = 38° 45'$, $C = 46° 33' 39''$.

Then *to find* A and B

	By (174)	By (175)
$\frac{1}{2}(a - b) = 17° 36' 30''$	log cos 9.979160	log sin 9.480738
$\frac{1}{2}(a + b) = 56° 21' 30''$	log sec 0.256493	log csc 0.079606
$\frac{1}{2} C = 23° 16' 49''.5$	log cot 0.366266	log cot 0.366266
$\frac{1}{2}(A + B) = 75° 57' 33''.8$	log tan 10.601919	
$\frac{1}{2}(A - B) = 40° 10' 54''.3$		log tan 9.926610
$A = 116° 8' 28''.1$		
$B = 35° 46' 39''.5$		

To find c

	By (175)
$C = 46° 33' 39''$	log sin 9.861060
$a = 73° 58'$	log sin 9 982769
$A = 116° 8' 28''.1$	log csc 0.046863
$c = 51° 00' 15''.8$	log sin 9.890532

Ans. $\begin{cases} A = 116° 8' 28''.1 \\ B = 35° 46' 39''.5 \\ c = 51° 00' 15''.8 \end{cases}$

---

92. Case II. *Given two angles and the included side, A, B, c.*

Pass to the polar, solve that by Case I., and then pass back.

Or, by means of $(171)_1$ and $(171)_3$ find a and b, thus:

$$\tan \tfrac{1}{2}(a-b) = \frac{\sin \tfrac{1}{2}(A-B)}{\sin \tfrac{1}{2}(A+B)} \tan \tfrac{1}{2}c \qquad (176)$$

$$\tan \tfrac{1}{2}(a+b) = \frac{\cos \tfrac{1}{2}(A-B)}{\cos \tfrac{1}{2}(A+B)} \tan \tfrac{1}{2}c \qquad (177)$$

Then find C by $(144)_2$,

$$\sin C = \frac{\sin c}{\sin a} \sin A. \qquad (178)$$

---

93. **Case III.** *Given two sides and the angle opposite one of them*, as a, b, A.

Find B from $(144)_2$, then c from $(171)_1$ and C from $(171)_2$. The equations are

$$\sin B = \sin A \sin b \csc a \qquad (179)$$

$$\tan \tfrac{1}{2}c = \frac{\sin \tfrac{1}{2}(A+B)}{\sin \tfrac{1}{2}(A-B)} \tan \tfrac{1}{2}(a-b) \qquad (180)$$

$$\cot \tfrac{1}{2}C = \frac{\sin \tfrac{1}{2}(a+b)}{\sin \tfrac{1}{2}(a-b)} \tan \tfrac{1}{2}(A-B) \qquad (181)$$

Equations (154) will give c and C directly by means of natural functions.

This case, like the corresponding one in plane triangles, may have two solutions, one solution, or no solution, as already shown in Article 79. There will be two solutions when

$$A < 90°, \qquad a + b < 180°, \qquad a < b,$$

or $$A > 90°, \qquad a + b > 180°, \qquad a > b.$$

If $\sin B = 1$ in (179), there will be one solution, and the side a will be perpendicular to the side b.

If $\sin B > 1$ there will be no solution.

94. **Case IV.** *Given two angles and the side opposite one of them*, as A, B, a.

Pass to the polar, solve that and then pass back. Or, solve directly by means of $(144)_1$, $(171)_1$, $(171)_4$. There may be two solutions.

---

95. **Case V.** *Given the three sides*, a, b, c.

Solve by means of equations (165).

---

96. **Case VI.** *Given the three angles.*

Solve by means of equations (166).

---

97. **Area of the spherical triangle.** Let A, B, C, be the angles of the triangle, R the radius of the sphere, E the spherical excess, and K the area, then

$$E = A + B + C - 180^\circ$$

$$K = \frac{E}{180^\circ}\,\pi R^2 \qquad (182)$$

EXAMPLES.

1. Given $a = 70^\circ\ 4'\ 18''$, $b = 63^\circ\ 21'\ 27''$, $c = 59^\circ\ 16'\ 23''$, to find the angles A and B.

   Ans. $A = 81^\circ\ 38'\ 20''$, $B = 70^\circ\ 9'\ 38''$.

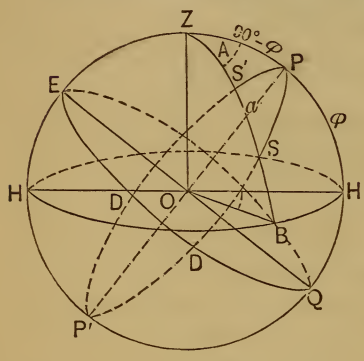
2. Given the three sides of a spherical triangle, $120^\circ\ 43'\ 37''$, $109^\circ\ 55'\ 42''$, and $116^\circ\ 38'\ 83''$; required the angles.

   Ans. $115^\circ\ 13'\ 26''$, $98^\circ\ 21'\ 40''$, $109^\circ\ 50'\ 22''$.

Applications of Spherical Trigonometry.

98. **Definitions.** *The celestial sphere* is the imaginary concave surface in which all the celestial bodies appear to be situated. Its radius is considered as infinitely long.

The sensible horizon is the circle in which a tangent plane to the surface of the earth cuts the celestial sphere.



The real horizon is the great circle in which a plane through the centre of the earth cuts the surface of the celestial sphere.

The Zenith of the observer is a point directly over his head in the surface of the celestial sphere. It is one pole of the horizon. Let O be the place of the observer, Z his zenith, then will HBH be his horizon.

The celestial equator or *equinoctial* is the great circle in which the plane of the earth's equator produced cuts the surface of the celestial sphere, as EDQ.

The axis of the earth is the imaginary line about which the earth rotates. The axis of the celestial sphere is the same line prolonged, as, POP'.

The poles of the equinoctial are the points where the earth's axis pierces the surface of the celestial sphere, as P and P'.

The ecliptic is the great circle of the celestial sphere cut by the plane of the earth's orbit.

The equinoxes are the points of intersection of the ecliptic and the celestial equator.

Hour circles or *circles of declination* are great circles passing through the poles of the equinoctial, as PSP'.

The celestial meridian of the observer is the great circle of intersection of the plane of the terrestrial meridian of the observer with the surface of the celestial sphere.

Vertical circles are great circles passing through the zenith of the observer, as ZSB.

The east and west points are where the vertical circles perpendicular to the meridian of the observer cut the horizon.

Prime verticals are verticals passing through the east and west points.

The obliquity of the ecliptic is the angle between the plane of the ecliptic and the plane of the equator, and is about 23° 27′.

The declination of a star is its distance north or south of the celestial equator. If S be the place of a star DS will be its declination. It corresponds to terrestrial latitude.

The polar distance of a star is the complement of its declination, as PS.

The right ascension of a star is the dihedral angle between the *hour circle* of the star and an established meridian. The established astronomical meridian passes through that equinox which is in the constellation Aries; and right ascension is measured from this meridian *east* through 360°. The right ascension and declination of celestial bodies are given in *nautical almanacs* or *ephemerides*.

The difference between the right ascensions of two stars is the angle between their hour circles. Thus, if S and S' are the positions of two stars, PS and PS' their hour circles, then will the difference between their right ascensions be SPS', which is measured by the arc DD on the equator between the respective hour circles.

The azimuth of a star is the angle between the meridian of the place and the vertical through the star, as HB, or HOB = the angle A at Z.

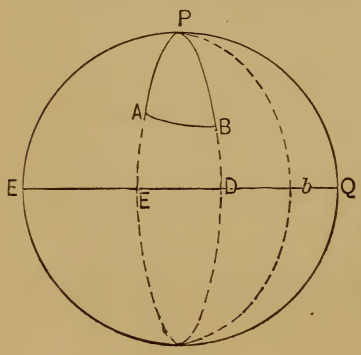
The hour angle of a star is the angle between the hour circle of the star and the meridian of the place, as ZPS. When given in degrees, it may be reduced to hours by dividing by 15, or to minutes by multiplying by 4; for the earth revolves through 15 degrees in one hour, or $\frac{1}{4}$ of a degree in one minute.

The altitude of a star is its angular elevation above the horizon, as BS.

The zenith distance of a star is the complement of its altitude, as ZS.

---

99. *To find the shortest distance between two places on the earth's surface given by their latitudes and longitudes.*



Let A and B be the places, DB the latitude of B, EA that of A, bD and bE, their respective longitudes; then in the triangle APB, we have the angle $APB = ED$ = the difference of their longitudes; PB and PA the co-latitudes, or polar distances. The arc AB will be the arc of a great circle. Hence there will be given two sides and the included angle, and may be solved by Case I., Article 91.

EXAMPLES.

1. The latitude of the government post-office at New York City is 40° 42′ 44″ N., its longitude 74° 0′ 24″ W.; the latitude of Liverpool is 53° 25′ N., and longitude 3° W., what is the shortest distance between them in miles on the earth's surface, the earth being considered a sphere whose radius is 3,956 miles.

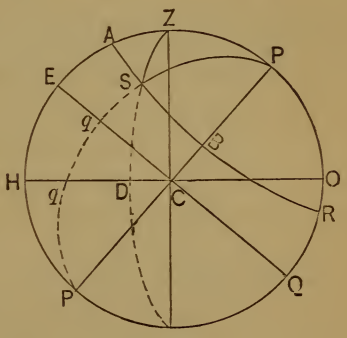
Ans. 3,305 miles.

2. The latitude of San Francisco being 37° 48′ N., its longitude 122° 23′ W., and that of New York, that given in example 1, find the shortest distance on the earth's surface between them.

Ans. 2,562 miles.

---

100. *The latitude of a place equals the elevation of the pole above the horizon.*



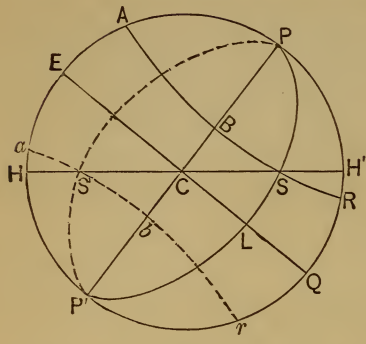
For if Z be the zenith of the observer, EZ will be his latitude; and P being the pole of the sphere, HO the horizon, we have $ECP = ZCO = 90°$. Taking ZCP from both, leaves $ECZ = PCO =$ latitude.

---

101. *To find the time of sunrise at any given place on a given day.*

Let C be the place of the observer, HCH' his horizon, RBA the small circle in which the sun appears to move, P the pole, EQ the

equator, PCH' the latitude of the observer. The sun will appear to rise when it comes into the horizon at S. Then in the triangle SLC, right angled at L, we have $SL =$ the declination of the sun, $SCL =$ the co-latitude of the observer; hence, CL which measures the hour angle CPL, may be found from one of Napier's rules, giving



$$\sin CL = \tan Lat. \,.\, \tan Dec.$$

The sun would be six hours in describing the arc BA, and when at A it would be noon; hence CPL reduced to time, will be the time of rising *before* six o'clock. The same rule applies to any other celestial body. If rba be the path of the star, the time of rising will be six hours less the hour angle $S'Pb$.

EXAMPLES.

1. Required the time of sunrise at Hoboken on the longest day of the year; the latitude of the place being 40° 43′ 48″. The greatest declination of the sun will be 23° 27′.

$Lat. = 40° 43′ 48″$	log tan 9.935027
$Dec. = 23° 27′$	log tan 9.637265
$hour\ angle = 21° 55′ 54″$	log sin 9.572292

$= 1h.\ 27m.\ 43.6s.$ which taken from $6h.$ gives $4h.\ 32m.\ 16.4s.$

2. Required the time of sunrise in the preceding example, on the shortest day of the year.

Ans. $7h.\ 27m.\ 43.6s.$

[The declination of the sun will be 23° 27′ south; and the preceding computation will give the time *after* six o'clock.]

3. Required the length of the longest day at Hoboken.

[It will be found that the number of hours in the length of the day will be twice the hour of sunset; and hence the length of the night will be twice that of the sunrise.]

4. When the declination of the sun is 23° 27′, at what latitude will the sun not rise?

[If the declination be north it will rise at that place at midnight, or in other words be above the horizon 24 hours; but if the declination be south it will just come to the horizon at noon.]

5. At what time will the sun rise for a place on the equator?

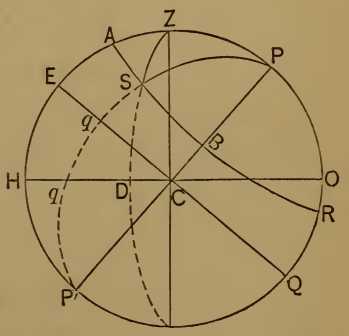
[It will be found to be independent of the declination of the sun, and be at six o'clock.]

6. When the declination of the sun is 15° N., what will be the latitude of the place at which the sun rises at 4 o'clock?

[No allowance in these examples is made for refraction, semi-diameter of the sun, ellipsoidal form of the earth, or change in declination from mean noon.]

---

102. *To find the time of the day from the altitude of the sun.*



Let C be the place of the observer, S the sun (or star), ABR its path; then will EZ be the latitude of the observer, ZP = the co-latitude, DS = the altitude of the sun, ZS = co-altitude or zenith distance, qS = the declination of the sun, PS = co-declination or polar distance, and ZPS = the hour angle, sought, which reduced to time will be the hours before noon if S be east of the meridian, and after noon if it be west of the meridian. In the tri-

angle ZPS, three sides are known to find the angle P. Hence equation $(163)_1$ gives

$$\cos \tfrac{1}{2}ZPS = \sqrt{\frac{\sin s \sin (s-a)}{\sin b \sin c}},$$

where

$$2s = (90^\circ - L) + (90^\circ - A) + (90^\circ - D) = 270^\circ - (L + A + D)$$

$$\therefore\ s = 135^\circ - \tfrac{1}{2}(L + A + D)$$

$$a = 90^\circ - A,\ b = 90^\circ - L,\ c = 90^\circ - D.$$

EXAMPLE.—In latitude 40° 21′ N., when the declination of the sun is 3° 20′ S., and its altitude 36° 12′, what is the time of day, after noon?

Ans. 2*h.* 17*m.* 20*s.*

---

103. *To find the azimuth at extreme elongation of a star.* If S', in the figure in the next article, be the star, then at the extreme elongation $ZS'P$ will be a right angle, PS' the polar distance of the star, and ZP the co-latitude, and by Napier's rules we have

$$\sin (90^\circ - \delta') = \sin (90^\circ - \varphi) \sin A,$$

or

$$\cos \delta' = \cos \varphi \sin A;$$

$$\therefore\ \sin A = \frac{\cos \delta'}{\cos \varphi}$$

EXAMPLE.—If $\delta' = 88^\circ\ 41'\ 24''$, $\varphi = 40^\circ\ 43'\ 48''$, required A. *Ans.* $A = 2^\circ\ 0'\ 28''$.

---

104. *Given the right ascensions of two stars and their declinations, to find their common azimuth angle when in the same vertical, and their hour angles.*

Let S and S' be the respective positions of the stars.

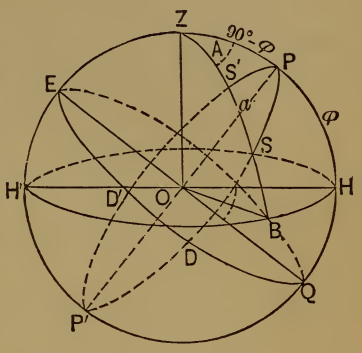
φ = the latitude of the place = EZ,

δ = the declination of $S = DS$,

δ' = the declination of $S' = D'S'$,

$\alpha - \alpha'$ = the difference of their right ascensions = SPS',

a = the side SS',



then

$ZP = 90° - \varphi$ = the co-latitude,

$PS = 90° - \delta$ = the polar distance of S,

$PS' = 90° - \delta$ = the polar distance of S',

$A = PZS = HOB$ = the azimuth.

From equation $(154)_1$

$$\cos a = \sin \delta \sin \delta' + \cos \delta \cos \delta' \cos (\alpha - \alpha') \quad (183)$$

Let m and N be auxiliary quantities and have such values that

$$m \sin N = \sin \delta' \quad (184)$$

$$m \cos N = \cos \delta' \cos (\alpha - \alpha') \quad (185)$$

which may be done since by these two equations the two unknown quantities m and N may be found.

Dividing (184) by (185),

$$\tan N = \frac{\tan \delta'}{\cos (\alpha - \alpha')}; \quad (186)$$

also

$$m = \frac{\sin \delta'}{\sin N}, \text{ or } = \frac{\cos \delta' \cos (\alpha - \alpha')}{\cos N}. \quad (187)$$

Substituting (184) and (185) in (183) reducing and substituting m from (187) gives

$$\cos a = m \cos (\delta - N) = \frac{\sin \delta' \cos (\delta - N)}{\sin N}. \quad (188)$$

From ZPS', equation $(144)_1$,

$$\sin S' = \frac{\sin A \cos \varphi}{\cos \delta'} \quad (189)$$

and from SPS',

$$\sin S' = \frac{\cos \delta \sin (\alpha - \alpha')}{\sin a}; \quad (190)$$

dividing and reducing, gives

$$\sin A = \frac{\cos \delta \cos \delta' \sin (\alpha - \alpha')}{\cos \varphi \sin a}, \quad (191)$$

which gives the required azimuth.

To find the hour angle $ZPS' = t$

From equations (156)

$$\begin{aligned} \sin t \cot A &= \sin (90^\circ - \varphi) \cot (90^\circ - \delta) \\ &\quad - \cos (90^\circ - \varphi) \cos t \\ &= \cos \varphi \tan \delta - \sin \varphi \cos t. \end{aligned}$$

Let

$$\left.\begin{aligned} b \sin B &= \sin \varphi \\ b \cos B &= \cot A \end{aligned}\right\} \quad (192)$$

then

$$b = \frac{\sin \varphi}{\sin B}, \qquad \tan B = \frac{\sin \varphi}{\cot A}. \quad (193)$$

Substituting (192) in the equation immediately preceding, we have

$$b \sin t \cos B + b \sin B \cos t = \cos \varphi \tan \delta$$

or

$$\sin (t + B) = \cot \varphi \tan \delta \sin B, \quad (194)$$

by means of which t may be determined.

EXAMPLE.

To find the common azimuth, and the corresponding hour angle for Polaris and ε Ursæ Majoris at the place whose latitude is 40° 43′ 48″.5, and longitude 0*h*. 12*m*. 8*s*. east of the meridian of Washington. (This is very nearly the latitude and longitude of Stevens Institute, Hoboken, N. J.)

Since the right ascension and declination of the stars is continually, though very slowly, changing, it will be necessary when great accuracy is desired, to ascertain these quantities for the date of the proposed observation. Making the computation for January 1, 1884, we find from the Nautical Almanac for that date that for

Polaris the declination was..... 88° 41′ 24″.87,
and the right ascension..... 1*h*. 16*m*. 14.29*s*.
and for ε Ursæ Majoris..... dec = 56° 35′
R. A. = 12*h*. 53*m*.

The quantities for either star may be primed. Let $\delta' = 88°\ 41'\ 24''.87$, $\delta = 56°\ 35'$. Then $\alpha - \alpha'$ reduced to arc will be 174° 11′ 25″.6. The work may be arranged as follows:

		By (186) log		By (188) log		By (191) log
$\delta' =$	88° 41′ 24″.87	tan	11.640856	sin	9.999886	cos 8.359028
$\delta =$	56° 35′	.....			.....	cos 9.740334
$\alpha - \alpha =$	174° 11′ 25″.6	sec	0.002236*n*		.....	sin 9.005275
$N =$	91° 18′ 11″	tan	11.643092*n*	csc	0.000113	
$\delta - N = -$	34° 48′ 11″	.....		ccs	9.914844	
$a =$	34° 43′ 11″	.....		cos	9.916843	csc 0.244159

		By (193)		By (194)		
$\varphi =$	40° 43′ 48″.5	sin	9.814579	cot	10.064971	sec 0.120450
$A =$	0° 10′ 9″	tan	7.470148	.....		sin 7.470146
$B =$	0° 6′ 37″.3	tan	7.284727	sin	7.284727	
$\delta' =$	88° 41′ 26″.87	.....		tan	11.640859	
$t + B =$	5° 36′ 55″	.....		sin	8.990557	
$\therefore t =$	5° 30′ 18″					
	= 0*h*. 22*m*. 1*s*.					

This method may be used by surveyors for finding the true meridian, and is useful when time enters the computation, for an ordinary time piece may be used. Thus, observe when Polaris is in the same vertical with ε Ursæ Majoris (the second star in the handle of the great dipper from the bowl); then in 22 minutes the polar star will be on the meridian.

The hour angle of Polaris when it and α Ursæ Majoris have the same azimuth is $2h.\ 11m.\ 36s.$

When Polaris and δ Ursæ Majoris are in the same vertical the common azimuth is $0°\ 26'\ 28''.6$ and the corresponding hour angle of Polaris is $0h.\ 37m.\ 10.45s.$

The hour angles of α and δ Ursæ Majoris will be much less than that of Polaris when the azimuths are equal.

SOLUTION OF OBLIQUE TRIANGLES.

65. $\cos A + \cos B = 2 \cos \frac{1}{2} (A + B) \cos \frac{1}{2} (A - B)$

66. $\cos B - \cos A = 2 \sin \frac{1}{2} (A + B) \sin \frac{1}{2} (A - B)$

67. $\sin^2 A - \sin^2 B = \cos^2 B - \cos^2 A = \sin (A + B) \sin (A - B)$

68. $\cos^2 A - \sin^2 B = \cos (A + B) \cos (A - B)$

69. $\tan A + \tan B = \frac{\sin (A + B)}{\cos A . \cos B}$

70. $\tan A - \tan B = \frac{\sin (A - B)}{\cos A . \cos B}$

EXPLANATION

OF

THE TABLES.

The arithmetical complement of a number is the remainder after subtracting it from 10. It is often used to avoid the necessity of subtracting one logarithm from another. Instead of subtracting a logarithm, we may *add* its arithmetical complement and subtract 10 from the result. Thus $a - b$ is the same as $a + (10 - b) - 10$.

The arithmetical complement is indicated by the abbreviation "ar co," or "a. c." Thus to find the logarithm of

$$\frac{\sin 50^\circ}{\cos 60^\circ},$$

we have

50°	log sin	9.884254
60°	log cos	9.698970
subtracting,		0.185284

or,

50°	log sin	9.884254
60°	ar co log cos	0.301030
adding,		10.185284
subtracting		10
gives		0.185284,

which is the same as the preceding result.

The logarithm of a number consists of two parts, a whole number called the *characteristic*, and a decimal called the *mantissa*. All numbers which consist of the same figures standing in the same order have the same mantissa, regardless of the position of the decimal point in the number, or of the number of ciphers which precede or follow the significant figures of the number. The value of the characteristic depends entirely on the position of the decimal point in the number. It is always one less than the number of

figures in the number to the left of the decimal point. The value is therefore diminished by one every time the decimal point of the number is removed one place to the left, and *vice versa*. Thus

Number.	*Logarithm.*
13840.	4.141136
1384.0	3.141136
138.40	2.141136
13.84	1.141136
1.384	0.141136
.1384	$\bar{1}$.141136
.01384	$\bar{2}$.141136
.001384	$\bar{3}$.141136
etc.	etc.

The mantissa is always positive even when the characteristic is negative. We may avoid the use of a negative characteristic by arbitrarily adding 10, which may be neglected at the close of the calculation. By this rule we have

Number.	*Logarithm.*
1.384	0.141136
.1384	9.141136
.01384	8.141136
.001384	7.141136
etc.	etc.

No confusion need arise from this method in finding a number from its logarithm; for although the logarithm 6.141136 represents either the number 1,384,000, or the decimal .0001384, yet these are so diverse in their values that we can never be uncertain in a given problem which to adopt.

The first table contains the mantissas of logarithms, carried to six places of decimals, for numbers between 1 and 9999, inclusive. The first three figures of a number are given in the first column, the fourth at the top of the other columns. The first two figures of the mantissa are given only in the second column, but these are understood to apply to the remaining four figures in either column following, which are comprised between the same horizontal lines with the two.

If a number (after cutting off the ciphers at either end) consists of not more than four figures, the mantissa may be taken direct from the table; but by interpolation the logarithm of a number having six figures may be obtained. The last column contains the average difference of consecutive logarithms on

the same line, but for a given case the difference needs to be verified by actual subtraction, at least so far as the last figure is concerned. The lower part of the page contains a complete list of differences, with their multiples divided by 10.

To find the logarithm of a number having six figures :—Take out the mantissa for the four superior places directly from the table, and find the difference between this mantissa and the next greater in the table. Add to the mantissa taken out the quantity found in the table of proportional parts, opposite the difference, and in the column headed by the fifth figure of the number; also add $\frac{1}{10}$ the quantity in the column headed by the sixth figure. The sum is the mantissa required, to which must be prefixed a decimal point and the proper characteristic.

Example.—Find the log of 23.4275.

For 2342 mantissa is	369587
" diff. 185 col. 7	129.5
" " " " 5	9.2

Ans. For 23.4275 log is 1.369726

The decimals of the corrections are added together to determine the nearest value of the sixth figure of the mantissa.

To find the number corresponding to a given logarithm.—If the given mantissa is not in the table find the one next less, and take out the four figures corresponding to it; divide the difference between the two mantissas by the tabular difference in that part of the table, and annex the figures of the quotient to the four figures already taken out. Finally, place the decimal point according to the rule for characteristics, prefixing or annexing ciphers if necessary. The division required is facilitated by the table of proportional parts, which furnishes by inspection the figures of the quotient.

Example.—Find the number of which the logarithm is 8.263927

		8.263927
First 4 figures 1836 from		263873
	Diff.	54.0
Tabular diff. = 236	∴ 5th fig. = 2	47.2
		6.80
	6th fig. = 3	7.08

Ans. No. = .183,623,000.

The number derived from a six-place logarithm is not reliable beyond the sixth figure.

At the end of the first table is a small table of logarithms of numbers from 1 to 100, with the characteristic prefixed, for easy reference when the given number does not exceed two digits. But the same mantissas may be found in the larger table.

The logarithmic sine, tangent, etc. of an arc is the logarithm of the natural sine, tangent, etc. of the same arc, but with 10 added to the characteristic to avoid negatives. This table gives log sines, tangents, cosines, and cotangents for every minute of the quadrant. With the number of degrees at the left side of the page are to be read the minutes in the left-hand column ; with the degrees on the right-hand side are to be read the minutes in the right-hand column. When the degrees appear at the top of the page the top headings must be observed, when at the bottom those at the bottom. Since the values found for arcs in the first quadrant are duplicated in the second, the degrees are given from 0° to 180°. The differences in the logarithms due to a change of one second in the arc are given in adjoining columns.

To find the log. sin, cos, tan, or cot of a given arc.: Take out from the proper column of the table the logarithm corresponding to the given number of degrees and minutes. If there be any seconds multiply them by the adjoining tabular difference, and apply their product as a correction to the logarithm already taken out. The correction is to be *added* if the logarithms of the table are increasing with the angle, or *subtracted* if they are decreasing as the angle increases. In the first quadrant the log sines and tangents increase, and the log. cosines and cotangents decrease as the angle increases.

Example.—Find the log sin of 9° 28′ 20″.

Log sin of 9° 28′ is	9.216097
Add correction 20 × 12.62	252
Ans.	9.216349

Example.—Find the log cot of 9° 28′ 20″.

Log cotan of 9° 28′ is	10.777948
Subtract correction 20 × 12.97	259
Ans.	10.777689

To find the angle or arc corresponding to a given logarithmic sine, tangent, cosine, or cotangent.—If the given logarithm is found in the proper column take out the degrees and minutes directly; if not, find the two consecutive logarithms between which the given logarithm would fall, and adopt that one which corresponds to the least number of minutes; which minutes take out with the degrees, and divide the difference between this logarithm and the given one by the adjoining tabular difference for a quotient, which will be the required number of seconds.

With logarithms to six places of decimals the quotient is not reliable beyond the tenth of a second.

Example.—9.383731 is the log tan of what angle?

Next *less* 9.383682 gives		13° 36′
Diff.	49.00 ÷ 9.20 =	05″.3
	Ans.	13° 36′ 05″.3

Example.—9.249348 is the log cos of what angle?

Next *greater* 583 gives		79° 46′
Diff.	235 ÷ 11.67 =	20″.1
	Ans.	79° 46′ 20″.1

The above rules do not apply to the first two pages of this table (except for the column headed cosine at top) because here the differences vary so rapidly that interpolation made by them in the usual way will not give exact results.

On the first two pages, the *first* column contains the number of seconds for every minute from 1′ to 2°; the minutes are given in the *second*, the log. sin. in the *third*, and in the *fourth* are the last three figures of a logarithm which is the difference between the log sin and the logarithm of the number of seconds in the first column. The first three figures and the characteristic of this logarithm are placed, once for all, at the head of the column.

To find the log sin of an arc less than 2° given to seconds.—Reduce the given arc to seconds, and take the logarithm of the number of seconds from the table of logarithms, and *add* to this the logarithm from the fourth column opposite the same number of seconds. The sum is the log sin required.

The logarithm in the fourth column may need a slight inter-

polation of the last figure, to make it correspond closely to the given number of seconds.

Example.—Find the log sin of 1° 39′ 14″.4.

1° 39′ 14″.4 = 5954″.4	log 3.774838
	add $(q - l)$ 4.685515
	Ans. log sin 8.460353

Log tangents of small arcs are found in the same way, only taking the last four figures of $(q - l)$ from the *fifth* column.

Example.—Find the log tan of 0° 52′ 35″.

52′ 35″ = (3120″ + 35″) = 3155″	log 3.498999
	add $(q - l)$ 4.685609
	Ans. log tan 8.184608

To find the log cotangent of an angle less than 2° given to seconds.—Take from the column headed $(q + l)$ the logarithm corresponding to the given angle, interpolating for the last figure if necessary, and from this *subtract* the logarithm of the number of seconds in the given angle.

Example.—Find the log cotan of 1° 44′ 22″.5.

	$q + l$ 15.314292
6240″ + 22″.5 = 6262.5	log 3.796748
	Ans. 11.517544

These two pages may be used in the same way when the given angle lies between 88° and 92°, or between 178° and 180°; but if the number of degrees be found at the *bottom* of the page, the title of each column will be found there also; and if the number of degrees be found on the *right hand* side of the page, the number of minutes must be found in the right hand column, and since here the minutes increase upward, the number of seconds on the same line in the first column must be *diminished* by the odd seconds in the given angle to obtain the number whose logarithm is to be used with $(q \pm l)$ taken from the table.

Example.—Find the log cos of 88° 41′ 12″.5

	$(q - l)$ 4.685537
4740″ − 12″.5 = 4727.5	log 3.674631
	Ans. 8.360168

Example.—Find the log tan of 90° 30′ 50″.

$1800'' + 50'' = 1850''$

$q + l$	15.314413
log	3.267172
Ans.	12.047241

To find the arc corresponding to a given log sin, cos, tan, or cotan which falls within the limits of the first two pages of the table.

Find in the proper column two consecutive logarithms between which the given logarithm falls. If the title of the given function is found at the top of that column read the degrees from the top of the page; if at the bottom read from the bottom.

Find the value of $(q - l)$ or $(q + l)$, as the case may require, corresponding to the given log (interpolating for the last figure if necessary). Then if q = given log and l = log of number of seconds, n, in the required arc, we have at once $l = q - (q - l)$ or $l = (q + l) - q$, whence n is easily found.

Find in the first column two consecutive quantities between which the number n falls, and if the degrees are read from the *left hand* side of the page, adopt the *less*, take out the minutes from the second column, and take for the seconds the difference between the quantity adopted and the number n. But if the degrees are read from the *right hand* side of the page, adopt the *greater* quantity, take out the minutes on the same line from the right-hand column, and for the seconds take the difference between the number adopted and the number n.

Example.—11.734268 is the log cot of what arc?

$q + l$		15.314376
q		11.734268
$\therefore$ n =	3802.8	3.580108
For 1° adopt	3780. giving 03′	
Difference	22″.8	

Ans. 1° 03′ 22″.8 or 178° 56′ 37″.2.

Example.—8.201795 is the log cos of what arc?

$q - l$		4.685556
q		8.201795
$\therefore$ n =	3282″.8	3.516239
For 89° adopt	3300. giving 05′	
Difference	17″.2	

Ans. 89° 05′ 17″.2 or 90° 54′ 42″.8.
